KG International

MOVING THE WORLD

KG® PRODUCT
CATALOGUE

RELIABLE | SUSTAINABLE | PERFORMANCE

Our Quality Statement

We at KGI are fully committed to offering a comprehensive range of bearings and power transmission solutions in major industrial segments, so that our valued customers can achieve better quality, better productivity, more profits and a higher level of competitiveness in their market.

We accomplish this by continuously striving to achieve a higher level of professionalism internally, enhanced service & support and by continuously improving our business processes.

KGI is also committed to supporting the communities within which we operate. We believe in the practice of social responsibility and encourage similar behaviour in our employees and external providers. We support the conservation of the physical environment and the prevention of wastage and pollution at our facilities.

Introduction

KG International

MOVING TO
THE NEXT
50 YEARS
1968-2018

MOVING THE WORLD

50 years ago, a dream led to what is today a movement; a movement called KG International that is going strong-based on the beliefs, principals and ethics of the founding Chairman Mr. Kedar Gupta who founded the business in India way back in 1968.

The tiny acorn that germinated from an idea, a potential foreseen, is today a mighty oak in the shape of KG International of Jebel Ali Free Zone, Dubai. Sprawling over 55 countries in 5 continents, with a team size of over 100; KGI believes in forging relationships that last.

It has taken passion, determination, steely resolve and belief to create this reality, to make KGI a company favoured the world over for its quality, reliability, customer centricity and range on offer.

Kedar Gupta
Founder and Chairman
KGI Group

Rohit Gupta
CEO
KGI Group

A global family growing stronger

We choose to be a relationship-focussed company and prefer to work on a long-term basis with all our associates. By adding value through our knowledge-based expertise, we generate synergy through near partner-like associations, not only with our customers, but also with our external providers.

We have set examples for others to follow; be it exploring new markets or developing innovative strategies to service our customer's requirements. For us, customer service goes beyond the mere development of required products; we provide reliable solutions.

Our belief in our values is further reinforced by the trust gained over the years, from our associates spread worldwide. However, our greatest reward is our expanding global network of happy customers and external providers. While we seek new associations, strengthening existing relationships is our priority.

Our guiding principle is 'movement'

We provide cost-effective and customized solutions to help you with everything from standard bearings, special bearings to complete power transmission solutions, all under one roof. With a footprint in five continents and presence in 50+ countries, we are strategically located in Jebel Ali Free Zone, Dubai to offer world-class logistics support to our global customers.

KGI operates in 55 countries across 5 continents. We provide timely and efficient service everywhere you are. We are one of the pioneers in making Dubai an engineering component hub.

We lead the market because we serve

For almost five decades now, our motivation has been our desire to continuously outperform and exceed expectations. Our goals have always been high, our ambitions challenging and ethics demanding, as our focus continues to be our customers. From technical support and guidance, to on-time deliveries, all our systems are aligned to meet our customer's specific requirements.

Our Quality Management System has adhered to ISO Standards since 1999 and is currently following the ISO 9001:2015 version accredited by Lloyd's Register Quality Assurance (LRQA).

Our commitment to perfection has yielded exceptional results. Today, we are amongst the world's leading bearing companies, and this does not happen overnight. It has to be strived for and earned the harder way. The secret to success is our straightforward policy, which we never deviate from, i.e. service without compromise.

A movement gathering momentum

We believe that global competitiveness is the result of investments in modern technology, infrastructure, people, and systems. To ensure seamless workflow and management of our business processes, we have automated, integrated and centralized independent activities into a single operation.

Our in-house R&D and quality control procedures ensure that KG bearings are produced strictly in accordance with international standards. Regular on-the-job training and skill enhancement programs ensure that the KGI team is always up-to-date with the latest in technology and business practices.

Bearings Introduction

The History of Bearings

The idea of using a rolling element to move heavy items dates back to 1900 BC. This was done by the ancient Egyptians, who used logs to roll large stone blocks closer to pyramid construction sites.

The earliest bearings were manufactured using lignum vitae, a very heavy, hard and natural oily wood, native to Central America and the West Indies. This wood's natural oil assisted the manufacturing process by acting as a cutting fluid. These bearings found use in "wet" applications such as propeller-driven vessels, water-wheels, and pumps, etc. Lubrication was done using tallow or other animal fats.

The Industrial Revolution of the 18th century brought about widespread usage of iron in industrial processes. It also introduced the steam engine as a practical source of power, and created a demand for new types of machinery, which in turn required specialized bearings. These were the reasons that forced the industry then, to look for alternative materials to produce bearings that could match performance requirements.

In the latter half of the 19th century, Henry Bessemer developed a new steel-making process, which was more economical. As a result, this period saw a greater reliance on steel as a raw material for the production of better quality bearings.

The 20th century has been witness to a bearings revolution, which was brought about by modern-day inventions, such as motorcars, domestic appliances, agricultural and industrial machinery, robotics and computers, etc. The bearing industry has kept pace by adapting to the new technology and materials, to produce more precise, durable, and specialized bearings.

Classification and Types of Rolling Bearings

Rolling Contact Bearings can be categorized in many ways. One is based on the end use of the bearing e.g., agricultural, automotive, industrial, etc. However, considering technical parameters and construction, there are two ways to classify Rolling Contact Bearings:

On the basis of their design for specific load management

- **Radial bearings**

Designed for mainly radial load applications, i.e. when load direction is perpendicular to the shaft axis.

- **Axial (Thrust) Bearings**

Capable of supporting mainly axial (thrust) loads, i.e. when load direction is parallel to the shaft axis..

On the basis of the type of rolling elements

- **Ball Bearings**

Undoubtedly the most common type of bearings, they find usage in numerous applications that may range from in-line skates to computer hard drives. Since these bearings can handle both radial and axial (thrust) loads, they find maximum usage in applications that involve relatively small loads.

Ball Bearings are classified into Deep Groove, Angular Contact or Thrust Bearings. They can be further categorized on the basis of the number of rows, i.e. single row or double row. Specifically, for Thrust Ball Bearings, specific classification is done on the basis of directional usage, i.e. single direction or double direction.

At times, Ball Bearings are also categorized on the basis of the relationship between the bearing rings and rolling elements, the shape

of bearing rings, or on the basis of used accessories.

- **Roller Bearings**

These bearings are more suitable for applications involving relatively higher loads, and can handle both types of loads, i.e. radial and thrust.

Roller Bearings can be classified according to the shape of rollers used, as Spherical Roller, Tapered Roller, Cylindrical Roller or Needle Roller Bearings.

Bearing's Classification on the basis of the shape of the Rolling Elements

Design and Features of Rolling Contact Bearings

Generally, Rolling Contact Bearings comprise of an inner ring, an outer ring, rolling elements (balls or rollers) and a rolling element retainer (cage). It is the rolling elements and rings that bear the applied load (at the contact points of rolling elements and raceways); the cage does not bear any direct load. Its function is to hold the rolling elements at an equal distance from each other and prevent their fall out.

To achieve optimal performance from any bearing, it is important to properly define and understand the application requirements very judiciously.

BALL BEARING

ROLLER BEARING

Deep Groove Ball Bearings

Deep Groove Ball Bearings offer multiple options that serve a wide range of applications.

They typically consist of an inner ring, outer ring, balls and cage. variants are available with steel shields, rubber seals (contact/non-contact type), snap-ring grooves with snap-rings, and a variety of cage types.

Deep Groove Ball Bearings are mainly of two types

- Single Row
- Double Row

These bearings are designed for radial, axial, and also composite load applications.

Deep Groove Ball Bearings offer

- uni or bi-directional load carrying capability
- very high speed rotation
- very good running accuracy
- low noise and low friction torque

Deep Groove Ball Bearings are also classified as

- Miniature Ball Bearings

Bearings with an outside diameter lesser than 9 mm.

- Extra Small bearings

Bearings with an outer diameter greater than or equal to 9 mm, and with bore diameter lesser than 10 mm.

Angular Contact Ball Bearings

The raceway of both inner and outer rings of Angular Contact Ball Bearings are designed to maintain a specific contact angle between the balls and raceways, in the radial plane.

Standard cage materials for this type are pressed steel, high strength brass or synthetic resin. In comparison to a Deep Groove Ball Bearing, an Angular Contact type generally carries a higher number of rolling elements (balls), and is capable of sustaining radial, axial or composite loads.

Angular Contact Ball Bearings are classified into three sub-categories

- **Single Row**
They have three different contact angle classifications

Contact Angle Symbol	Contact Angle
A	30°
B	40°
C	15°

- **Double Row**
They have two different contact angle classifications

Contact Angle Symbol	Contact Angle
None	20°
A	30°

- **Combination Type**
Generally, Single Row Angular Contact Ball Bearings are used in combination of two or more units. Three different combinations are available.

Contact Angle Symbol	Contact Angle
Back - to - Back	Bidirectional axial
Face - to - Face	Bidirectional axial
Tandem	Unidirectional axial

Self-Aligning Ball Bearings

Self-Aligning Ball Bearings are designed to contain the inner ring and ball assembly in the outer ring with a spherical raceway. Due to their special construction, these bearings can tolerate small angular misalignments of shaft upto 2.5° - 3° depending upon the bearing series. This misalignment could either be due to usage, or it could be due to a mounting error.

Cylindrical Roller Bearings

Cylindrical Roller Bearings probably have the most simple construction in the roller bearing category. These bearings are suitable for carrying relatively higher loads, at high-speed applications.

There is a linear contact between the rolling elements and bearing rings. This comparatively larger contact surface area enables Cylindrical Roller Bearings to handle a much greater radial load, compared to a Ball Bearing. However, their axial load bearing capacity is limited. Numerous variants of this bearing type are available to match specific application requirements, for e.g. NU, NJ, N, NF, NUP, NN, etc.

Compared to the single row type, Double Row Cylindrical Roller Bearings are used for higher speed and greater accuracy applications, e.g. in machining centres, etc.

Cylindrical Roller Bearings are generally used along with Plummer Blocks, and are available with two bore types, i.e. cylindrical and taper. Their cages are made of either pressed steel or polyamide resin.

Tapered Roller Bearings

As the name implies, the rolling elements and raceways (of the outer and inner rings) of these bearing are made with a tapered profile. These bearings can be separated into components, i.e. the outer ring (cup), and the combined inner ring and roller assembly (cone).

Tapered Roller Bearings are further classified into

- **Single Row**
A Single Row Tapered Roller Bearing can support a combined radial and axial load. However, if an application has a bi-directional

axial load, then two Single Row Tapered Roller Bearings can be used together in a back-to-back or face-to-face mounting pattern.

- **Double Row**
Double Row Tapered Roller Bearings are specially made to sustain radial and bi-directional axial loads.
- **Four Row**
Four Row Tapered Roller Bearings can support much heavier radial and impact loads, in addition to the standard capabilities of Double Row Tapered Roller Bearings.

Spherical Roller Bearings

In Spherical Roller Bearings, the raceway of the outer ring is designed to have a spherical profile, whose centre coincides with the bearing's centre point.

This type of bearing is a self-aligning type. Hence, can be used for applications where a misalignment of shaft may arise either due to an erroneous mounting or due to shaft

deflections. The outer ring generally has lubrication holes and grooves. These bearings are suitable for very high radial load applications, and a moderately high level of bi-directional axial load.

Spherical Roller Bearings have two bore types

- Cylindrical Bore
- Tapered Bore

Axial (Thrust) Ball Bearings

Thrust Ball Bearings are designed to handle axial loads only. They should not be used for any radial load applications.

A bearing ring mounted on a shaft is called Shaft Washer, and the one mounted on a housing is called Housing Washer.

Thrust Ball Bearings are of two types

- **Single Direction type**
Suitable for handling only uni-directional axial loads.

- **Double Direction type**
Suitable for handling bi-directional axial loads.

Thrust Ball Bearings are not suitable for high-speed applications. At high-speeds, a sliding movement between balls and raceways can occur, which may result in smearing. Further at high-speeds, centrifugal forces expel lubricating oil. This fact alone restricts the acceptability of Thrust Ball Bearings for high-speed applications.

Thrust Roller Bearings

Thrust Roller Bearings are preferred for axial load applications, as they provide higher rigidity in comparison to other types.

Thrust Roller Bearings are of three types

- Thrust Cylindrical Roller Bearings
- Thrust Tapered Roller Bearings
- Thrust Spherical Roller Bearings

A Thrust Spherical Roller Bearing is a self-aligning bearing. In service, it allows a maximum shaft misalignment

of about 2°. The contact angle helps this type of bearing to handle a small amount of radial load.

Lubrication of these bearings needs to be done carefully, since large sliding contact areas results in smearing. Care should be taken to maintain the least rated minimum load on this bearing, to avoid smearing.

Types, Construction and Features of Rolling Contact Bearings

CHARACTERISTICS			BEARING TYPES	Load Carrying Capacity	High Speed Suitability	Rigidity	Misalignment Permissibility	Quiet Operation
Deep Groove Ball Bearings

Selection of Rolling Contact Bearings

to study both the bearing and its application parameters. Generally, since a shaft diameter is known beforehand, the focus should be on application parameters. The flowchart on the following page shows a sample selection procedure.

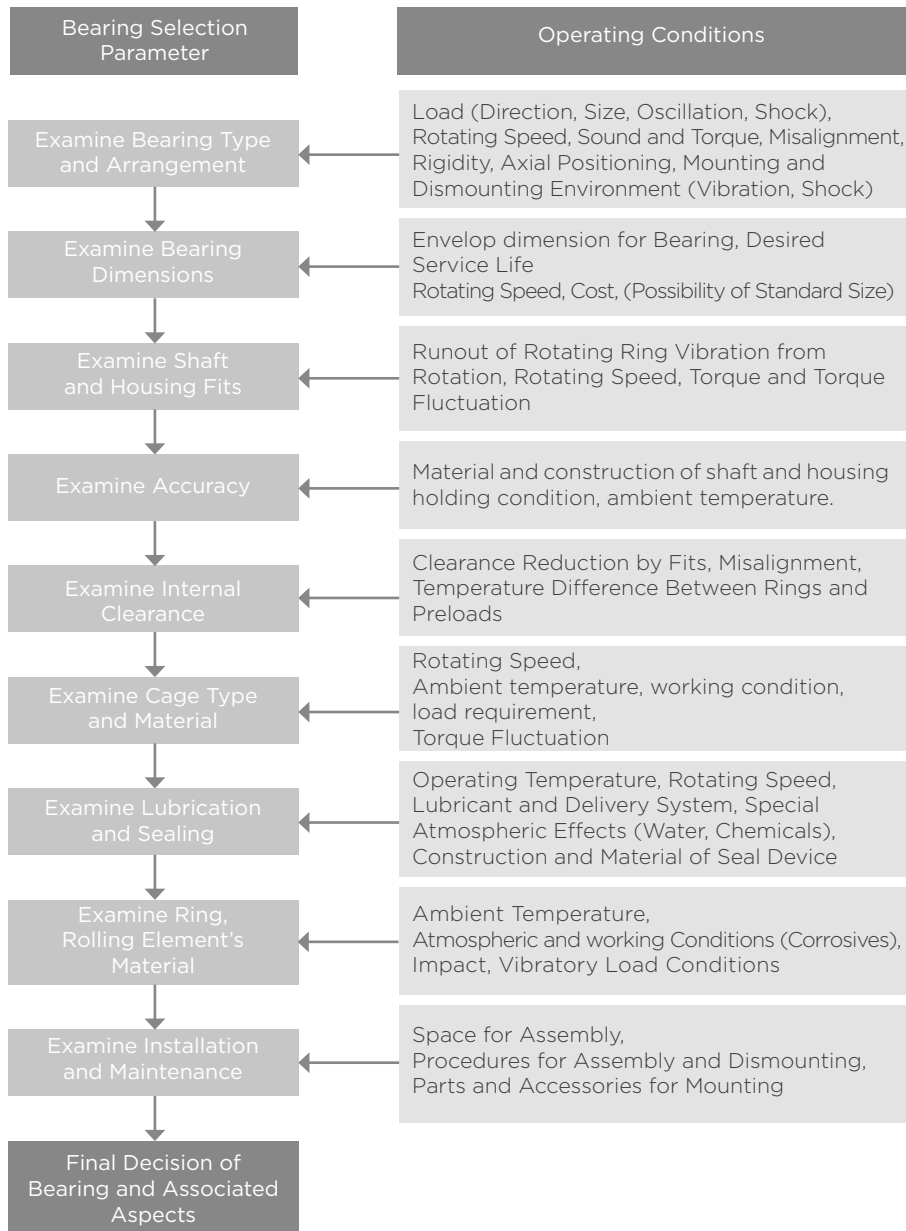

Major bearing selection parameters are

- load types (i.e. radial, axial, or moment)
- the magnitude of these loads on the bearing
- limiting speed
- noise and torque levels
- rigidity and chances of misalignment
- bearing life
- accuracy

The performance and service life of any machine or equipment is directly related to the performance of the bearings used in it. There is no standard rule of bearing selection for different applications. To avoid unnecessary costs and loss of machine time, a systematic effort must be made to consider maximum parameters for selecting the most suitable bearing for an application.

With diversification in bearing designs, their application range has also expanded. With multiple choices available, to make the best selection, it becomes mandatory

Material for Rolling Contact Bearings

Under operative conditions, rolling elements roll and slide between a bearing's outer and inner rings, subjecting the contact areas to high and repetitive stress, leading to material fatigue after some usage. This fatigue can lead to an eventual bearing failure.

Material for Rings and Rolling Elements

The choice of material to be used in bearing rings and rolling elements depends on the typical design and application requirements.

Basic and desirable material characteristics

- higher hardness
- good wear resistance

- higher rolling contact fatigue resistance
- dimensional stability
- good mechanical strength

Bearing performance is greatly influenced by the material used in its construction. Generally, material for a bearing rings and its rolling elements is selected according to the application conditions. To meet higher hardness requirements, high carbon chrome bearing steel is mainly used. For a corrosive atmosphere, stainless steel is preferred. If good tolerance to high temperature is required, then high-speed steel is preferred. Similarly, Ceramic Bearings are used for certain special applications.

Chemical Composition for Various Types of Bearing Steels

The material for KG Rolling Bearings is normally high carbon, through-hardened chromium steel with a good degree of cleanliness. For special applications that involve shock loads and reverse bending stresses, certain bearings made with case-hardened steel are also available.

*High Carbon Chrome Bearing Steel - SAE 52100/100Cr6/SUJ2/GCr15

Chemical Composition (%)						
C	Si	Mn	P	S	Cr	Mo
0.90-1.10	0.15-0.35	≤ 0.25-0.45	≤ 0.027	≤ 0.025	1.30-1.60	≤ 0.10

*Case Hardening Steel

Standard	Symbol	Chemical Composition (%)							
		C	Si	Mn	P	S	Ni	Cr	Mo
SAE	8620	0.18-0.23	0.15-0.35	0.70-0.90	≤ 0.035	≤ 0.040	0.40-0.70	0.40-0.60	0.15-0.25
	4320	0.17-0.22	0.15-0.35	0.45-0.65	≤ 0.035	≤ 0.040	1.65-2.00	0.40-0.60	0.20-0.30

*Stainless Steel

Symbol	Chemical Composition (%)						
	C	Si	Mn	P	S	Cr	Mo
SUS440C	0.95-1.20	≤ 1.0	≤ 1.00	≤ 0.040	≤ 0.030	16-18	≤ 0.75
SUS420C	0.15-0.36	≤ 1.0	≤ 1.0	≤ 0.04	≤ 0.030	12-14	-

* These shown values are only for reference.

Material for Cages

Similar to the desirable characteristics of the material for rolling elements, the material used in the fabrication of bearing cages should also possess certain desirable properties.

Desirable cage properties

- good wear resistance
- dimensional stability
- good mechanical strength

There are three standard types of cages

- Pressed cages, that use cold-rolled steel

- Machined cages, that use high tensile strength brass castings or carbon steels

- Polyamide cages, that use polyamide resins

Once again, the choice of material for bearing cages is made according to the operating conditions. For instance, brass cages should not be used in environments with ammonia, or at temperatures above 300° C, as this may cause season cracking. Similarly, polyamide cages should only be used in the temperature range of -40° to +120° C. They should not be used in a vacuum, as the resin may become brittle due to dehydration.

Lubrication

of lubricants, which can vary with the type of application.

When in use, friction due to moving parts may generate heat, which reduces lubricant viscosity, which further deteriorates lubricant quality and its subsequent evaporation.

Selection of both, i.e. proper lubricant and the correct lubrication method is critical to a bearing's performance and operational life. Generally, rolling bearings use either an oil-based or a grease-based lubricant. Some applications may call for more specialized lubricants such as graphite, PTFE or molybdenum disulfide-based varieties.

Bearing rings, rolling elements and cage are subjected to high levels of rolling and sliding friction. This friction may damage the bearing, and eventually reduce its service life. Proper lubrication can reduce frictional damages and extend a bearing's productive life.

Lubricants separate rolling and sliding surfaces with a very thin film of oil. The applied load is carried by pressure generated within the fluid; frictional resistance to motion arises entirely from the shearing of the viscous lubricating fluid. A bearing's performance and service life largely depend on the appropriate selection

Essentially, lubricants have following roles to play

- reduce rolling friction between rolling elements and raceways.
- minimize sliding friction between
 - the rolling end and guide faces of bearing
 - the rolling elements and cage
 - the cage and raceway guiding surfaces
- prevent foreign particle contamination
- prevent rust and corrosion
- remove heat from bearing

- uniformly distribute stress to the rolling contact surfaces
- provide some relief from impact loads

Desirable characteristics of a good bearing lubricant are

- nil moisture content
- non-reactive properties with bearing materials
- nil impurities
- good temperature stability
- non-corrosivity
- good wear and friction resistance
- high mechanical stability
- load pressure resistance

Guide to Selecting Oil and Grease Lubricants

Application Conditions	Grease	Oil
Temperature	Not suitable for high temperature (100°C to 120°C)	Suitable for high temperature (with circulating cooling)
Speed	Low to medium speeds	Suitable for high speeds (depends on lubrication method)
Load	Light to medium loads	Suitable for high loads
Housing design maintenance	Simple	Complicated (need to consider oil leak prevention)
Centralized lubrication	Possible	Easy
Dust filtration	Not possible	Possible (circulating lubrication provides a filter to trap dust)
Rolling resistance	Large	Small (correct oil quantity must be maintained)

Lubricating Oil

Since it is only a thin oil film that separates the contacting surfaces, it is important for this film to have correct viscosity. Emphasis is on correct viscosity, as both lower or higher viscosity of a lubricating medium at operating temperatures can affect bearing performance.

Low viscosity can cause the lubricating film to break, leading to a lubrication failure. At the same time, higher viscosity increases the operational torque, which results in power loss and an abnormal rise in temperature.

Viscosity in itself changes with temperature. Higher the temperature, lower will be the viscosity. This relationship between viscosity and temperature is an important criterion for selection of lubricating oil for a particular application.

For correct lube oil selection, apart from viscosity, solidification temperature and flash point (temperature) are also important considerations. This information is critical for determining and maintaining the correct operating temperature, for the selected lubricating oil.

In order to maintain optimum lubrication and good service performance of bearings, lubricating oil samples must be tested at regular intervals. Lubricating oil should be changed, if any alteration in colour or viscosity is noticed, or the presence of impurities is observed.

Bearing Types and Proper Viscosity of Lubricating Oils

Bearing Type	Viscosity at Operating Temperature
Ball Bearings, Cylindrical Roller Bearings	Over 13 mm ² /s
Tapered Roller Bearings, Spherical Roller Bearings	Over 20 mm ² /s
Spherical Roller Thrust Bearings	Over 32 mm ² /s

Lubricating Grease

Grease is generally the preferred lubricant for rolling bearings. The reason is simple; no special sealing devices are required to prevent drain off at standstill, or even otherwise. But grease increases bearing wear, due to its tendency to accumulate abrasive particles that maybe generated during normal bearing usage.

Grease is made using three components

- base oil
- thickener
- additives

The actual lubricant is the base oil, thickener gives it consistency and additives impart performance enhancing characteristics. All three are important for every bearing application.

Usually, mineral oils are used as base oils for grease. For improved heat resistance and stability, synthetic oils, like silicone and diester are used. Generally, grease with low viscosity

base oil is good for low loads and low temperature applications, whereas for high temperature and heavy load applications, grease with high viscosity base oil is preferred.

Thickeners are added to base oils for imparting consistency to the blend, and together they account for 80%-90% of grease content. Essentially, it is a sponge like structure, with a weak bonding of fine fibres or particles.

Additives are added to impart performance enhancing properties to grease. Extreme pressure additives may improve load and impact resistance, while anti-oxidant additives protect grease from oxidation and thermal deterioration. Likewise, rust prevention additives enhance rust resistance capabilities.

The amount of grease to be used for lubrication varies with the bearing size; other parameters like operating speed and temperature, type and amount of load, ambient conditions, etc. are also important considerations. Generally, a minimum level of 30%, and on the upper side up to 50% of a bearing's internal volume (free space) should be filled with grease. If lithium-based greases are being used, then up to 90% of available space can be filled up.

Typical Lubricating Greases for Bearings

Name of Grease	Grease maker	Base Oil	Thickener	Penetration
Daphne Eponech No. 2	Idemitsu Kosan	Hydrodesulfurized wax	Lithium	280
Beacon 325	Exxon Mobil	Diester Oil	Lithium	280
Polyrex EM	Exxon Mobil	Mineral Oil	Polyurea	285

Polyacrylic Rubber or ABS Resin

- Do not mix different types of greases
- If Sodium thickener grease is mixed with water, it will soften and may leak

Handling of Bearings

Rolling Bearings are machined elements that work in a high precision environment; their correct handling is critical to obtain an optimal performance.

Recommendations for storage

- store at a cool and dry place, away from direct sunlight and moisture
- store at a raised base (around 30 cm) above the floor, to avoid dust accumulation
- maintain a stable temperature in the storage area (around 20° C)
- maintain humidity levels (below 65%) to prevent rusting
- do not stack bearings in many layers to avoid falling and consequential damage
- use bearings on a first-in and first-out basis, to use older packs first

- take maximum care to save bearings from impact shocks like dropping etc., as they can damage the raceways, rolling elements or the cage

Recommendations for transportation and handling

- protect a bearing from falling when transporting it
- handle heavy bearing cases with forklift or hoist
- always cover bearings with clean packing paper / polybag
- to avoid contamination, do not open the bearing pack until just prior to installation
- avoid direct human contact with a bearing, use proper tools and wear gloves to protect them from rust or contamination

Mounting of Bearings

Bearing performance not only depends on a careful selection of good quality bearing type, but also on its proper mounting.

Mounting Preparation

Before mounting, following precautions must be taken

- tools and equipment should be prepared, cleaned and checked for any cracks or breakage
- the place for mounting should be clean and dry
- unpack the bearing just before mounting
- clean and check both shaft and housing for presence of nicks, burrs or any signs of physical damage
- measurements of shaft and housing size, roundness taper, surface finish, shoulder squareness etc., should be recorded and verified for conformity with design specifications
- in case of split housing, extreme care should be taken to avoid misalignment and deformation that maybe caused by tightening or over-tightening of mounting bolts

- the lubricant and its applicators should be properly cleaned and closed
- the method of cleaning the bearing and its relevant parts should be established and understood

As rust preventive oil is also a good lubricant, it should not be cleaned off, when the bearing is to be used for normal applications. If the bearing is to be used in a measuring equipment or at a high-speed application, rust preventive oil should be removed using a clean detergent oil. In any case, a bearing should not be left in the open (especially after removing rust preventive oil) for a long time.

Bearing Mounting Methods

Generally, the following bearing mounting methods are used in the industry.

A. Press-fit Method

Depending on the application requirement, either the inner ring (Fig. 1) or the outer ring (Fig. 2) or both the rings (as shown in Fig. 3) are press-fit using a jack, a hydraulic press, or a mounting fixture that has an end which matches the size of the respective ring(s). A plastic hammer should be used to drive the bearing on the shaft to minimize shock to the bearing.

B. Thermal Expansion Method

In this method, the inner ring is heated using an induction heater or a heating tank. This process eliminates the need to apply undue stress on the bearing, as a heated bearing expands and it can easily slide on the shaft. The heating temperature should not exceed 120°C, as it may reduce the hardness of the bearing steel.

After mounting, the remaining procedure should be completed smoothly and quickly. Further, the bearing should not be allowed to develop any residual misalignment, as it is hard to correct once it cools down. Similarly, a clearance may develop between the inner ring and shaft. To avoid this problem, the clamping nut should be re-tightened while the bearing is still hot, but cooling down.

The Thermal Expansion Method is generally used to mount bearings with a large bore size.

C. Adapter or Withdrawal Method

In this method, a tapered sleeve is inserted between a bearing's tapered bore and cylindrical shaft. Then using a locknut, the bearing is driven up the sleeve. This process is divided into several steps; the bearing's internal clearance, also known as residual clearance, should be measured each time. Before sliding the sleeve, the measured internal clearance is called initial clearance. The difference between the residual clearance and the initial clearance determines the amount of interference.

Dismounting of Bearing

Common Dismounting Tools

Dismounting Bearing with Oil Injector

The choice of method for bearing dismounting is largely dependent on the objective. For instance, if the bearing has to be disposed of, even a cutting torch can be used. However, if the bearing has to be re-used or a study has to be conducted on failure causes, it is pertinent to dismount it without any damage to the bearing or its parts, especially the raceways and rolling elements.

Before dismounting, the condition of the rotating parts, interference, and lubricants should be checked and recorded to find out the possible causes of failure and the corrective measures required to solve the problem.

Precautions to be taken before dismounting

- decide dismounting method in advance
- dismount under an expert's supervision
- check, prepare and keep ready required dismounting tools and equipment

Dismounting Bearing with Special Puller

Inner Ring removal using Induction Heater

Dismounting Bearing with Spanner Wrench

Bearing Pullers

Puller Attachment

Bearing Failures

It is an established fact that bearings do not break down abruptly. A diligent observant approach to identify warning signs of an imminent failure, can prevent machinery breakdowns and consequential losses.

At KGI, we take due care to deliver bearings that allow long storage life. Once the bearings arrive at the consumer's warehouse, their proper storage is important. To a limited extent, the rust-preventive oil coat on the bearings can protect them from corrosion. However, high relative humidity levels, or even substantial day-night temperature variations can expose bearings to moisture.

Normal use of bearings is accompanied by

- minor vibrations
- operating noise
- a slight increase in temperature due to operations
- electricity consumption
- lubricant deterioration over time

A sudden increase in general level of any of these parameters is a definite indication of an impending bearing failure or seizure. Overlooking any of these faults can lead to serious problems. It could severely damage principal equipment or even lead to a fire.

Failures causes are classified into three categories

- failures due to environmental factors
 - negligence in mounting, dirty working conditions, inadequate lubrication, over-loading, vibrations, over-speeding, over-heating, pollution.
- failures due to misapplication
 - incorrect selection of the type of bearing, or improper mounting
- failures due to the quality of the bearing itself
 - material fault quality, structure or steel composition
 - design and production fault internal geometry, cage or seal quality

The following pages only outline the environmental factors that cause 90% of bearing failures. Failures due to misapplication and bearing quality seldom occur. Moreover, their investigation and analysis require elaborate means of research and quality control.

Environmental Causes and Origins of Bearing Failures

Bearing failures occur due to many external causes, but they can be classified into four basic categories

Mounting Conditions

- improper tools and mounting procedures
- dirty mounting conditions
- mounting shock loads
- improper manufacturing of components
- surrounding the bearing with out of tolerance shafts and housings, misalignment, etc.

Operating conditions

- over-loading
- external vibrations
- over speeding
- shaft deflection (bowing)

Environmental conditions

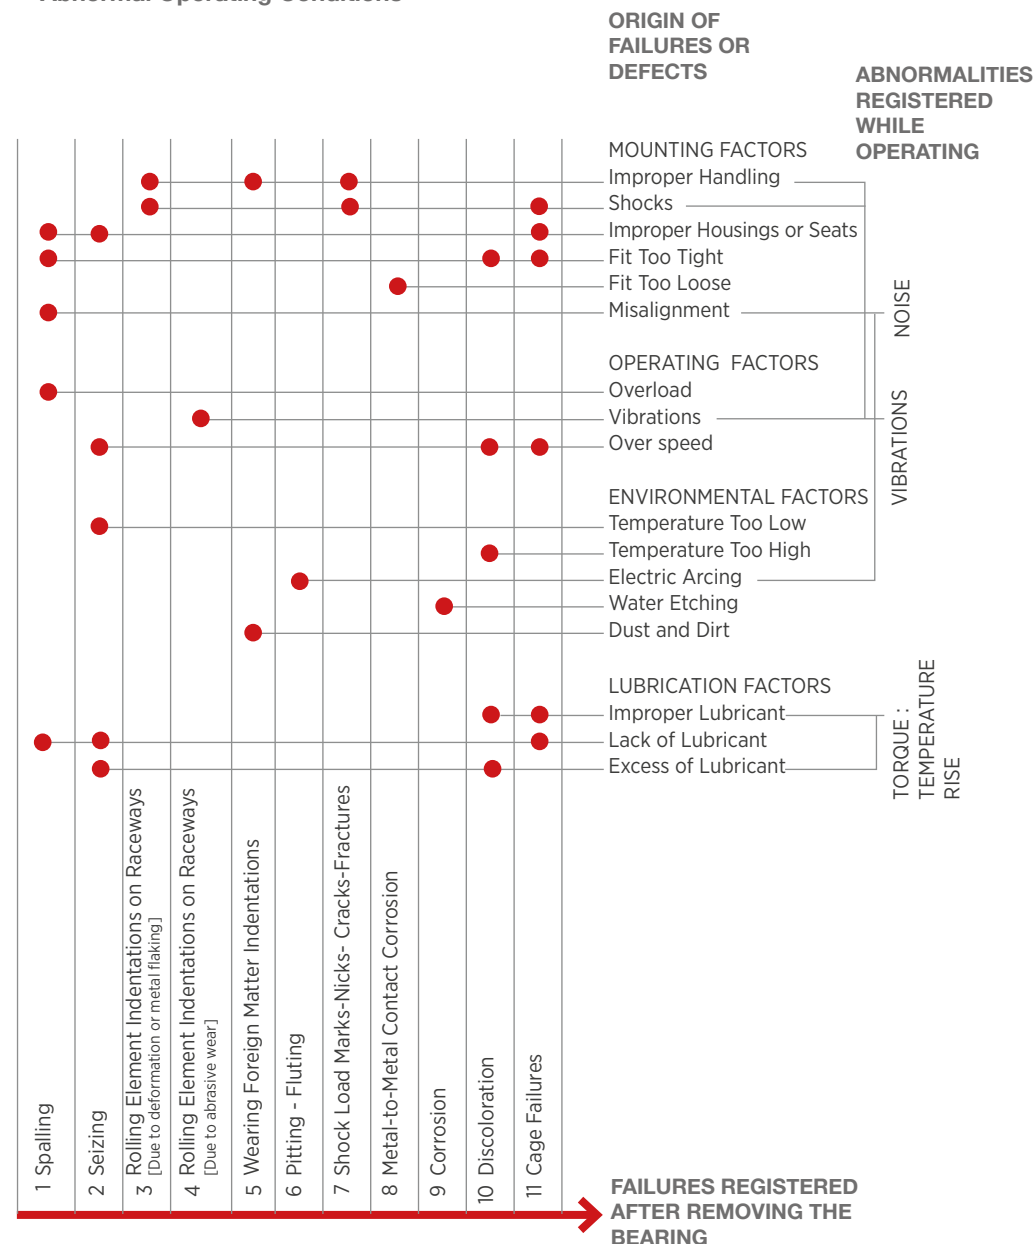

- too low or too high an ambient temperature
- electric arcing
- contamination from water, dust, chemicals, textile debris, etc.

Lubrication conditions

- improper lubricant
- inadequate supply of lubricant
- long re-lubrication interval

The chart on the following page should guide the user in identifying the probable cause of failures, and also assist in better failure management.

Diagnosis of Bearing's Abnormal Operating Conditions

Detection of a Bearing's Failure

Bearing users' main concern should be to detect the beginning of a failure, prior to equipment breakdown. Preventive maintenance is essentially the best remedy, but in certain cases the amount of time taken and the high expenses involved in reaching the bearing can be the deterrents. Though, for some applications preventive maintenance is a "must" (e.g., the aircraft industry, mine ventilation, etc.). Even though, the amount of fatigue in a bearing is difficult to evaluate from external indications, however as a thumb rule, users should consider the approaching end to a bearing's useful life, once external indications become detectable.

External Indications of Damage

A bearing rotating under functional conditions will exhibit certain "normal parameters" such as operating temperature, noise and vibrations. Their exact levels are dependent on several factors: load, speed, lubrication, type of bearing, etc. Abnormally high levels of "normal parameters" should be considered as a warning of a probable failure.

Deviations from the "operating norms" established under "operating

conditions" for any of the following, should signal the need for preventive maintenance or at least a close examination to ascertain the cause.

- **Vibrations**

These can be detected by hand or with electronic equipment (frequency or amplitude analyser). An alert operator should stop the machine.

- **Noises**

Some abnormal noises can be heard immediately, such as those due to the rolling element's indentations because of improper mounting; others increase progressively. Noise indicates an incipient failure and varies in intensity and frequency with the extent of the damage. The damage due to unbalanced loads is generally inaudible since their frequency is identical to the rotating assembly's frequency.

- **Temperature rise**

All operating bearings are subjected to temperatures above the ambient, which vary according to the type of mounting. Any rise beyond the normal level is an indication of the beginning of failure.

- **Increase of rotational torque**

Even when mounted on bearings, all rotation systems produce a resistance torque. An increase in this torque, is accompanied by an eventual temperature rise, which indicates an alteration in the bearing's performance.

Interpretation of External Indications

Vibration

- Spalling
- abrasive wear due to foreign particles
- corrosion
- unbalanced loads due to bearing wear
- excessive clearance
- under-tightening of a ring

Noise

- indentations of rolling element
- Spalling
- False brinelling (indentations due to vibrations)
- foreign particles
- corrosion
- elimination of internal clearance due to excessive press fit
- Cage or rolling element failure

Temperature rise

- excess or lack of lubricant
- elimination of the internal clearance
- thrust overloading due to improper mounting

Abnormal running torque

- cage distortion
- lubricant deterioration
- seal damage or displacement

Preventive Control Procedures, and Means of Control

Frequency of control

It essentially depends upon the expected reliability, the material usage, and several other factors

which may be specific to each user. Sampling controls based on the bearing's life expectancy should be regularly performed.

External control means

Some control instruments that detect unusual vibrations are available, e.g., "sonic meters". In any case, a "reference level" should be determined for random comparison, to detect variance.

Failure Identification

Failure identification

It is not always easy to detect failures; though the following steps can be helpful

- record significant facts noticeable on the bearing, and its surrounding components
- identify all probable failure causes
- from the identified causes, select only those causes that match maximum abnormal performance parameters

Before removal

Carefully observe the following, before initiating the removal or dismounting process

- presence of dirt
- temperature increase due to lubricant loss
- noise level
- torque level
- evolution of the bearing deterioration
- orientation of bearing in assembly

After removal

Examine the following before cleaning the bearing; otherwise, a proper condition analysis maybe difficult.

- the condition of cages and rolling elements
- wash bearing, and strain liquid to check presence of particles
- keep lubricant, seals and shields for examination
- keep track of bearing and ring mounting location
- check shaft and housing fits
- examine the mounting surface, e.g. the shaft and its housings.
- examine the shoulders for out of shape squareness, or presence of debris, rust etc.

Types of Failures

1. Spalling - Origin Aspects

Spalling can be found on raceways as well as on rolling elements. It can be deep (fatigue spalling), or shallow. In both cases, causes and symptoms are different.

Spalling Appearances

Fatigue Spalling

Bearings have a limited life expectancy. The operating loads to which they are subjected determine their fatigue life.

Spalling Fatigue Mechanism

When a bearing is subjected to loads, pressures in the raceway and rolling element contact area can be very high. Maximum value shearing forces develop at some thousandths of an inch below the contact surface. These repetitive stresses, caused by the continuous travelling of the rolling elements, initiate the spalling process.

Small cracks may develop in the material, that start at the high stress point and progress to the surface. These cracks eventually join and cause the metal to flake in a rapidly expanding area.

Spalling Aspects

Spalling is a progressive phenomenon that increases more or less rapidly after the appearance of the first crack. Consequently, material spalling must be detected at its early stage; if left unchecked it can lead to a premature bearing failure.

Beginning of Spalling

In the initial stages, Bearing surface may develop some jointless fractures.

Even though the component profile may not change at this stage, but these cracks characterize an underlying fatigue.

Advanced Spalling

The fractures that had developed in initial stages start connecting together in a more advanced Spalling stage. The component profile may still not change, but the surface finish can get badly damaged. Some metal chips may flake and get mixed with the lubricant, and further accelerate destruction.

Final Spalling

In the final stages, the entire bearing surface gets spalled. Metal alterations caused by shearing forces get joined. Spalling destroys component profile, and effects bearing performance.

Shallow Spalling

Shallow spalling is typically characterized by spots that are more or less spread out in the load zone of the raceway surface. A microscopic examination of the effected zone

will show only superficial damage to metal.

Causes

Incorrect (insufficient or improper) lubrication is the basic cause of failure. The oil film may break due to the pressure created by the applied loads, thereby allowing contact between the rolling elements and raceways. This contact causes spot temperatures to rise, resulting in micro-welding, which further causes thin and superficial metal flaking. Shallow spalling is not material fatigue, it is a surface damage.

Spalling Locations

A. Load Zone

Identification

Spalling in the load zone affects most of the raceway width in a Roller Bearing, the bottom of race in a Deep Groove Ball Bearing, and both raceways of a Double Row Ball or Roller Bearing.

Causes

- limited or constant overloading
- improper or inadequate lubricant supply

Preventive Measures

- check bearing loads
- use an adequate supply of appropriate lubricant

B. Edge of Raceway

Identification

For Ball Bearings, the ball path runs from one side of the race to the other, around the non-rotating ring. The rotating ring has a ball path which is wider than usual. Cage fractures might occur in certain cases. For Tapered or Cylindrical Roller Bearings, fatigue areas can be detected on the edge of the raceways. The contact areas vary from one race edge to the other on both rings, but are diametrically opposed on each ring.

Causes

These failures are due to shaft and housing misalignment, that may get initiated either by an improper parallelism between the shaft axis and the housing bore generating line, or a wobble of the housing or shaft shoulders. This can also be observed from shaft bowing while operating. These faulty elements generate a heavy concentration of extra stresses leading to the development of premature bearing fatigue failures in overloaded areas.

Preventive Measures

Shaft and housing alignment should be carefully checked. Housings should be kept clean as some misalignments are due to the presence of foreign matter between the bearing faces and their contact shoulders.

C. On Non-Rotating Ring: Entire Raceways

Identification

A highly visible ball or roller path, or evident spalling even in the part opposite to the load zone, i.e. on the ring stationary in relation to the load, is a definite indication of spalling on the entire raceway.

Causes

Generally, the ring rotating in relation to the load should be mounted with a press fit. The tightness of the fit is dependent on the application requirements. The heavier the load, the tighter the fit. This is to prevent the ring from rotating on the shaft or in the housing.

An excessive interference fit can reduce or eliminate the internal bearing clearance and cause a preload to develop in addition to normal operating loads. This will cause all the rolling elements to come in contact with the raceways.

In addition to premature spalling, an excessive interference fit might generate internal ring stress. These unusual stresses, when added to

the Hertz pressures generate cracks, and even cause ring fractures.

Driving a Tapered Bore Self-Aligning Ball or Spherical Roller Bearing too far up a Tapered Adapter Sleeve would lead to a bearing distress as described above. This action over expands the inner ring, thus reducing or eliminating the internal clearance, and causing dangerous preloading of bearing.

Preventive Measures

Shaft guiding tolerances must be controlled, and gauges must be regularly checked against standards to eliminate chances of inaccurate measurements. When mounting Spherical Roller Bearings on Tapered Adapter Sleeves, a feeler gauge must be used to confirm proper internal clearance after mounting.

D. On Non-Rotating Ring: Particular Areas

Identification

The following are obvious symptoms of spalling on non-rotating ring

- **presence of intensive raceway spalling**
highly visible ball or roller path in two diametrically opposite areas, and sometimes in several points of the ring indicates intensive raceway spalling
- **presence of extended spalling around the raceway's circumference**
Spalling on one edge indicates that only this area has been working, hence it gets effected by

an extended spalling, all around the circumference

Causes

In the first case, distortion comes from the de-shaping of the housing, i.e. ovalization or triangulation. The outer ring follows the housing shape, and visibly evidences an excessive load in the areas corresponding to the squeeze. It can also be the result of foreign particles in the housing, which locally distort the rings. Self-aligning Ball Bearing Rings that are mounted in cast iron or steel housing units, are more susceptible to this kind of failure.

In the second case, damage is characteristic of a tapered housing, where only one ring edge is stressed. For Tapered or Cylindrical Roller Bearings, spalls are located in the highest squeezed area of the ring. For Self-aligning Ball or Roller Bearings, only one row of rolling elements runs with over stresses, hence it gets effected by an extended spalling around the raceway circumference.

Spalling located on this raceway can also be identified by "even fractures of ring edge", which may develop longitudinally because of high Hertz pressures.

Similar faults on inner rings are extremely rare as the distortion amplitude of shafts is not high

enough to produce that type of damage.

Preventive Measures

Housings should be machined only when material is heat stabilized. Along with a dimensional check, a

2. Seizing

Identification

Shallow metal flaking and the appearance of dark areas are significant representatives of a superficial transfer of the metal; original grind or hone marks tend to completely disappear in effected areas.

Brown patterns represent local or generalized over-heating. In more severe conditions, metal flaking, local melting and scoring, may deform the rolling elements.

Causes

Inadequate lubricant causes bearing seizure, as it may lead to a rupture of oil film, allowing metal-to-metal contact between the rolling elements and raceways, which

geometrical check should also be conducted on the housing to detect any deformation (roundness, off taper, etc.).

causes localized overheating and micro-welding.

Tapered Roller Bearings may seize under excessive preloaded condition or due to improper lubrication. It primarily effects the large roller end and the cone back face rib. Seizure often occurs when new equipment is started without appropriate lubrication.

If the bearing fit tolerances on seats are too loose, the shaft might rotate in the bore, or the outer ring might rotate in the housing. This also causes overheating, which could lead to bearing seizure.

High operating speeds can also cause bearing seizure. When the bearing load is light, rolling elements may not rotate instantaneously, either because of their inertia, or because of a rotation slow down caused by the lubricant. Friction due to rotation slow down leads to a temperature rise and consequential expansion leads to seizure between the rolling elements and raceways.

Seizing can also occur under a pure radial load, and more so when an excessively high viscosity lubricant is used. In Roller Bearings, the speed of the rollers which are not in the load zone decreases. They tend to skid, and eventually seize due to overheating of the bearing.

Preventive Measures

Lubrication advice from the equipment manufacturer, or the lubricant supplier, should be carefully followed; including lubrication at proper intervals.

Special care should be taken in greasing Tapered Roller Bearings. Lubricant must be introduced under the cage, towards the large end of rollers. For very high-speed

applications, only that lubricant which allows a prompt rotation of rolling elements should be used. In some instances, the use of a light preload might be required, at start up.

Other Preventive Measures

- investigate suitability of bearing type
- study preload, bearing clearance and fitting
- check precision of shaft and mounting
- improve mounting methods

3. Rolling Element Indentation on Raceways due to Deformation or Metal Flaking

A. On Ball Bearings

Identification

This fault can be identified by presence of ball bearings indentations either all around the perimeter of the races or on in an extended area. These indentations tend to be spaced according to the

ball spacing. Though the bottom of the dent is shiny, marks of original grind can also be seen.

Causes

This failure happens when bearing is subjected to excessively high shock loads, especially when either of the two rings (inner or outer) transfers this shock load to the other, through the balls.

If the shock generates an instantaneous load, which exceeds the known material elasticity limit, ball-race contact points get permanently dented. These dents increase noise levels and initiate future spalling.

Shock loads can be caused by

- **improper mounting method**
untrained operators may erroneously mount the bearing by hammering hard on one ring, to install the opposite ring
- **dropping of bearing on a hard surface**
in this case, the shock load due to accidental dropping gets transferred from the outer ring to the inner ring, through the balls

Preventive Measures

When mounting a bearing ring with a tight fit, impact force should not be applied to the other ring. If the tight fit ring is difficult to reach, it should be pressed with a tubular drift that has a proper shoulder diameter, squareness, and appropriate length.

To handle a bearing properly, a tubular drift can also help guide the ring during the mounting process and protect it from skewing and eventual damage to the shaft-end or housing.

B. On Cylindrical Roller Bearings

Identification

The presence of thin and deep grooves on raceways is considered as a general indication of this damage. More or less evenly spread, these grooves are parallel to their generating line, along with metal

pick up marks which get spaced according to the roller spacing.

Causes

When mounting and assembling, the small space between the diameter over (or under) the rollers and the race diameter of the opposite ring, might cause a pinching of these two elements.

Pinching causes mounting pressure and shock load that leaves scratches on the raceway of the opposite ring.

Preventive Measures

Never force one ring into another. When setting up a Shaft with an installed inner ring, it is recommended to rotate this shaft while mounting it into the outer ring. This rotation will help the rollers to be properly located, thereby prevent their pinching. Similar procedure should be followed while mounting an outer ring into a casting.

Insufficient lubrication (by grease) causes roller pinching and seizing. Hence, it is recommended to thoroughly grease these bearings before assembly, especially if they have been cleaned prior to mounting.

C. On Tapered Roller Bearings

Tapered Roller Bearing components (cup and cone) are mounted separately. This procedure reduces the chances of roller indentations. However, dents might appear if a cone is used to install the cup into its housing.

4. Rolling Elements Indentations on Raceways due to Abrasive Wear

Identification

The presence of dark or shiny indentations on bearing rings, which are more or less spread out and spaced according to the rolling element spacing, is considered as an evidence of this kind of damage. At times, several dents may be seen, which could be either superimposed or interrelated; irrespective, rolling element spacing is always noticeable on dents.

When examined under a microscope, indentations appear to be caused by a total removal rather than a back flow of material, since it occurs when shock loads are applied. In all cases, grinding marks disappear.

This failure is also called “false brinelling”.

Causes

In a stationary bearing, false brinelling is caused by vibrations or small amplitude oscillatory motion of balls between the races. However, it can also affect a rotating bearing, when both rings rotate simultaneously in total synchronism (e.g. Pilot Bearings).

Failure mechanism can be ascribed to

- both pressure and vibrations, which force lubricant out of the loading area causing metal-to-metal contact between rolling elements and races
- vibration stress causes micro-welding or micro-seizing and flaking of metal chips; oxidation impregnates these chips causing abrasive corrosion

This type of failure can be found in bearings

- subjected to intensive vibrations, even when they are mounted on stationary machines
- when both rings rotate at the same speed and consequently remain stationary, in relation to each other

This type of failure can appear in the following application conditions:

- on emergency electrical generators, which are connected to the same platform as the operating generator
- on “off” electrical motors, when mounted on operating machines
- on emergency fans connected with operating fans
- when unbraced machines are transported, and they are subjected to vibrations

Heavier equipment has more intense vibrations, causing greater risk to the bearings.

Preventive Measures

For stationary machinery

- care should be taken to block shafts, when transporting engines, generators or similar equipment, etc.
- periodically rotate (even slow) stationary machines in a vibration area; it will allow lubricant to spread out and avoid exertion of loads at the same spot of the raceways
- large bearings should be stocked flat and kept out of a vibration area (work stations)
- for infrequently operated machinery, it is prudent to use fluid lubricants; as they coat contact

surfaces better, in comparison to more viscous lubricants

For operating machinery

- low viscosity greases should be preferred as they are more efficient
- best resistance to contact corrosion is obtained by using low viscosity lubricating oils
- calcium and lead-calcium soaps are the best to control “false brinelling”

5. Wearing Foreign Matter Indentations

Identification

- by more or less intense development of a visible load path on raceways and rolling elements; raceways might show a continuous sectorial or longitudinal groove
- by excess clearance or by

unbalanced loads and vibrations that might occur

- by wearing of cage material
- by appearance of small dents on the ring path, with slightly rounded edges, which signify material deflection
- abnormal noise levels

Causes

These failures arise from a lack of protection, either when mounting or when operating the bearing.

Often operators do not realise the extent of destruction dust can cause to bearings. Regardless of its origin or texture, dust has a very high abrasive power, and with time, it can lead to excessive internal clearance and unbalanced loads which increase the rate of material fatigue.

Foreign matter indentations have the same origin as wearing. Inadequate protection allows foreign particles to penetrate the bearing. These particles constantly interfere between rolling elements

6. Pitting and Fluting

Identification

- **Pitting is represented by local metal smelting**
Microscopic examination will show pits with sharp edges that are joined in a string.

and raceways and can initiate small indentations to make the bearing operation noisier. The deterioration of raceway and rolling element surface finish accelerates material fatigue.

Preventive Measures

- when mounting, clean the shafts and housings
- ensure dust-free working areas
- do not wash new bearings
- protect bearings from dust when stocking
- use clean lubricants; cover lubricant containers when not in use
- wrap any mechanical element, when not in use
- prevent entrance of debris (textile, straws, fibres) or dust (coal, sand, metal chips, chemical products) into the bearings

- **Fluting is a sequence of narrow areas that look like grooves**
These grooves generally follow one another in raceway zones that are subjected to load, and may also appear on rollers

Causes

Pitting and fluting might occur on rotating machines which equip machine tools (railroad equipment or

engines), and the bearing is crossed by a current when it happens to be the only "earthing" link.

- **high amperage current**

Because of the short distance between the raceways and the rolling elements, crossing by high amperage current causes arcing (even through the lubricant). Arcing develops high temperature spots which melt the metal.

- **low amperage current**

Crossing by low amperage current causes alteration of metal surface

7. Shock Load Marks Nicks, Cracks and Fractures

Identification

This failure can be identified by the presence of

- shock load and tool marks on flat surfaces, rolling elements, and radii

texture, which appear as spaced grooves caused by rotation.

- **debris caught in the lubricant**
- **exposure to ambient humidity**
- **poor lubrication**

Preventive Measures

- ensure that machinery and elements are earthed
- check insulation and clean motor connectors to prevent current leakage
- improve sealing to prevent lubricant loss

- nicks and fractures of shoulders and ribs

Causes

When a bearing ring is subjected to a shock load, i.e. a load over its metal elasticity limits, it may get permanently dented. Shocks can also generate other problems like ring distortion and indentations. In some cases, shocks can cause nicks, cracks, or even fractures.

Cracks are very insidious for they may not be easily visible at first but they gradually cause metal chips to flake, which may penetrate the bearing and damage raceways and rolling elements.

The roller guiding elements of Cylindrical Roller Bearings are particularly sensitive to shocks, and consequently prone to this failure. In several cases, fractures have been noticed on Spherical Roller Bearings. When the outer ring swivels, one or several rollers can get dislocated in their cage pockets. Re-positioning them is not easy, as after dislocation the rollers tend to wedge in between the external face of the outer ring and one shoulder of the inner ring. When the rollers are dislocated, any shock load on the outer ring forcing it to swivel back gets transmitted through the rollers to the shoulder of the inner ring.

Fractures occur very often, and typically their spacing corresponds to the exact roller spacing.

Preventive Measures

- Rings and shoulders should not be hammered
- when mounting, always use a tubular drift between the hammer and bearing to evenly distribute shock forces around the ring circumference
- to mount Tapered, Cylindrical, or Spherical Roller Bearings on a shaft using an interference fit, the inner ring should be first expanded by heating in an approved manner
- to relocate the swivelled outer ring of a Spherical Roller Bearing, carefully rotate it while realigning the dislocated rollers
- do no close bearings forcefully

8. Ring Fractures

Identification

This fault is identified by fractures which maybe transverse or otherwise. These fractures can affect large ring areas also.

Causes

- due to the overloading of the outer ring
internal clearance may get eliminated; an internal preload may develop due to an excessive press fit of the inner ring on the shaft

- excessive radial stresses
it may result in multiple fractures of the ring
- excessive interference fit
transverse fractures of inner rings are caused by metal over stress due to excessive interference fit

Preventive Measures

To avoid this type of bearing failure, while mounting a bearing, care should be taken to

- ensure appropriate fitting tolerances
this is to avoid elimination of internal clearance, and prevent

- preloading of the Bearing
- use a Bearing with increased internal clearance
especially if heavy press fit method is employed to mount Bearing

9. Creep

coated with a brown paste, which is a result of mixing of rust and lubricant. Deep corrosion can break thin rings under load.

Identification

The appearance of pink, brown or black spots on the bore, or on the outside diameter or faces of the bearing indicates creep.

Microscopic examination of the area will show a deep attack on the surfaces. When rubbed, these spots leave rust marks. In cases of severe damage, rings and raceways get

Causes

An interference fit is required for rotating rings. An insufficient or non-existent fit will cause a slow turn of shaft, in relation to the inner ring (or the outer ring of the housing). This metal-to-metal motion picks up thin metal flakes from the bearing or shaft (or housing) and cause local seizing.

Flake particles tend to oxidize rapidly, in the absence of a lubricant. Their combined abrasive power further accelerates this process. Rough and granular housing surfaces are more prone to creep.

When bearings rotate or vibrate on their seats, contact corrosion also appears on their faces. This can happen when axial clamping is insufficient, or it loosens due to a

10. Corrosion

Identification

This fault is assumed to have set in when reddish or black spots appear, along with surface deterioration (including formation of cavities), due to a local or full oxidation of the bearing, including raceways, rolling elements, cage, face, bore outside diameter.

shim collapse, or a lock nut release. The corresponding bearing face tends to develop a hollow wear mark of the shoulder.

Preventive Measures

- both the geometry and the fitting tolerances of shafts and housings must be controlled to provide an adequate press fit
- ensure proper tightness of lock nuts, or housing end caps whenever used for mounting a bearing
- re-work the shaft surface as part of maintenance
- use special anti-seizing products on bearing seats and shoulders

Causes

- damage can be due to corrosive liquids or high humidity levels
- faulty sealing of the assembly

Corrosion can be systematic when bearings operate in a very damp environment and are subjected to frequent and long “on and off” operating cycles. When “on” the bearing’s temperature rises, causing the air in the housing to expand and

leak out. Long “off” period allows the bearing temperature to return to ambient levels and permits the humid air to flow back and cause condensation.

Repetitive “on and off” cycles progressively increase moisture deposits, which never get completely eliminated in the “on” phase. This moisture tends to mix with the grease and reduces the quality of

11. Discoloration

the lubrication. Eventually, corrosion spreads to all the internal elements.

The results of corrosion are similar to those of abrasive dust. Oxides flake under the rolling element loads, and the abrasive tendency of this mixture further accelerates bearing failure.

Preventive Measures

- use adequate shields or seals for improved protection
- control ambient conditions
- avoid direct exposure of seals and shields to liquid
- use lubricants that do not emulsify with water
- impart anti-rust treatment for extended periods of a bearing’s non-usage
- improve storage methods

Identification

This fault is identified by a brownish discolouration of the rings and rolling elements.

Causes

The most common cause of this failure is superficial oxidation and polymerization of lubricant, at high temperature. Heating of a bearing expands its rings to facilitate mounting. However, overheating

may cause the surface colour to develop a brownish discolouration. This burn-out might also occur if the bearing is heated by an open flame, or by a nonadjustable temperature stove, or by an uncontrolled oil bath.

Rise in bearing temperature and resultant discoloration can happen either due to internal reasons or external heat sources.

Besides facilitating movement, lubrication also maintains a thermal balance by evenly distributing internal heat, which eventually gets transferred to the external environment through the bearing's body. An inadequate supply or incorrect choice of lubricant can lower the thickness of the lubricant film between the rolling contact surfaces, leading to an internal thermal imbalance, and consequential rise in the bearing's temperature.

Also, if there is an elimination of clearance because of excessive press fit of rings in or on their seats, the preload increases assembly temperature.

Temperature rise can also happen under normal operating conditions, especially if excessive quantity of grease is forced into reduced spaces. Acting as a brake, it slows the rotation and causes the bearing to overheat.

An excessive rotating speed can also overheat the bearing and discolour the steel.

Temperature rise can also happen due to external sources like dryer cylinders, foundry motors, furnace wagons, etc. To maintain appropriate internal clearances, it is essential to consider these factors when deciding on the type of lubricant or on mounting tolerances.

Preventive Measures

- do not excessively grease
- choose appropriate lubricant
- frequently check lubricant supply
- check fits to avoid abnormal preloading
- allow the bearing to cool
- reduce external causes of temperature rise

12. Cage Failures

A. Distortion

Identification

Distortion of cages, or squeezing of cage pockets, or shock load marks are obvious failure signs. Identification of this failure is difficult, as sometimes symptoms are hidden by side effects such as over-heating, cage scoring due to rolling element friction, seizing, etc.

Causes

- exposure of bearings to physical shocks before mounting
- improper mounting

A ball bearing cage is very fragile; it is nearly flush with the ring faces and therefore prone to tool damage. A Tapered Roller Bearing cage protrudes beyond the cone front face, and use of improper installation tools can damage it. When bearings are hammered for mounting, tools may slip and distort the cage pockets, leading to pinching of the corresponding rolling elements.

Preventive Measures

Use a press to install a bearing whenever possible, to avoid severe impact and shock. When hammering cannot be avoided (for replacement essentially), use tubular drifts with the same shoulder diameter as the ring to be fitted. This procedure is highly recommended for a press fit mounting of a cone, especially when pushing on its front face.

B. Wearing

Identification

In this fault, cage pockets and the inside and outside diameters develop severe wear characteristics.

Causes

Abrasive particles might penetrate while mounting, but the chances of this to happen are more under operating conditions. In ball bearings, abrasion enlarges cage pockets, which leads to an increased

clearance and consequential physical imbalance. This imbalance enhances pocket wear, as the outside diameter of the cage now rubs against the outer ring, and its inside diameter rubs against the inner ring. In Tapered Roller Bearings, this imbalance may wear the cage bridge or even fracture it.

Preventive Measures

- carefully clean the bearing seat and its housing, to eliminate abrasive particles
- replace worn or damaged seals
- use special, and more efficient seals for Ball or Tapered Roller Bearings
- use clean lubricant, and store it only in covered containers when not in use

C. Fracture

Identification

Fractures can happen with or without scoring under the rolling elements.

Causes

- Cage fractures can be caused by
- severe cage damage during mounting
 - seizure due to improper lubrication
 - sudden acceleration or deceleration can lead to cage pocket distortion
 - cage over speeding (ball bearings)
 - elimination of internal clearance from excessive press fit

- excessive differential temperatures between the inner and outer ring
- constant change in direction caused by alternative or repetitive overturning moments on ball bearings
- differential speeds between balls cause repetitive pulling stresses on cages, leading to metal fatigue and eventual fractures
- deformation of housings caused by uncontrolled or unbalanced loads, etc.

Preventive Measures

- avoid cage damage during mounting
- use proper lubricant
- ensure sufficient lubricant quantity
- control acceleration and deceleration
- check maximum rpm (speed) required from bearing, and verify its design suitability
- check fitting tolerances and operating temperature
- use appropriate type of cage, for alternating overturning moments.

Bearing Data and Specifications

1. Bearing Technical Data

Dimensions

Bearings boundary dimensions are defined in the International Organization for Standardization (ISO):

Metric Radial Bearings except Taper roller bearing are in standard ISO 15

Metric Radial Taper Roller Bearings are in standard ISO 355

Metric Thrust Rolling Bearings are in standard ISO 104

Inch Taper roller bearings are in standard AFBMA Standard 19 (ANSI B3.19)

Basic Rating Life

The Basic rating life of bearing, calculation is in accordance with ISO 281 for Dynamic load rating and ISO 76 for Static load rating of Bearing.

Dynamic load rating: The load of Constant magnitude and direction that sufficiently large number of apparently identical bearings can endure for basic rating life of 1 Million revolutions.

Static load rating: The load under normal condition causes permanent deformation at contact points of approx..0.01 % of Rolling element diameter.

Speed

There is a limit to the speed at which rolling bearings can be operated, the temperature limit of the lubricant or the material of the bearing components sets the speed limit. The speed at which a bearing reaches its operating

temperature limit depends on the heat generated in the bearing any externally applied heat, and the amount of heat that can be transferred away from the bearing.

In this catalogue, 2 speeds are listed reference speed (thermal) and limiting speed (mechanical).

Reference speed: The speed capabilities of a bearing based on standardized reference values for the heat flow density as established in ISO 15312.

Limiting speed: The speed is determined lubrication, the form stability or strength of the cage, lubrication of cage guiding surfaces, centrifugal and gyratory forces acting on the rolling elements, bearing housing precision and other speed-limiting factors, such as shields/seals and the lubricant for sealed bearings.

2. Bearing Specifications

The Dimensions and Running Accuracy of Rolling Bearings has been standardized internationally in ISO as per different precision class, PN (P0), P6, P5, P4 etc.

2.1 Dimensional and Geometrical Tolerances of Rolling Bearings

2.1.1 Symbol definition

d	Nominal bearing bore diameter
Δdmp	Single plane mean bore diameter deviation (for tapered bore only as per theoretical inner bore)
Vdp	Bore diameter variation in a single radial plane
Vdmp	Mean bore diameter variation
D	Nominal bearing outside diameter
ΔDmp	Single plane mean outside diameter deviation
VDp	Outside diameter variation in a single radial plane
VDmp	Mean outside diameter variation
B	Nominal bearing width of inner ring
VBs	Deviation of a single inner ring width
ΔBs/ΔCs	Deviation of single inner ring/Outer ring width
C	Nominal bearing width of outer ring
VCs	Deviation of a single outer ring width
Kia	Radial runout of assembled bearing inner ring
Kea	Radial runout of assembled bearing outer ring
T	Nominal assemble bearing width
ΔTs	Deviation of assemble bearing width
Sia	Axial runout of assembled bearing inner ring
Sea	Axial runout of assembled bearing outer ring
ΔHs	Deviation in center height of bearing units

3. Bearing Clearances

Bearing clearance is defined as total distance through which one bearing ring can be moved relative to other in **Radial direction** which is called as **Radial internal clearance** and or in **Axial direction** which is called as **Axial internal clearance**.

Radial internal clearance

Axial internal clearance

Bearing Internal Clearance designations

- C1** Smaller than C2
- C2** Smaller than Normal (CN)
- CN** Normal Clearance, generally if there is no CN suffix in bearing number considered as CN
- C3** Greater than CN
- C4** Greater than C3
- C5** Greater than C4

Deep Groove Ball Bearings (Single and Double Row)

Deep Groove Ball Bearings

The versatility offered by Deep Groove Ball Bearings makes them most popular of all Bearing types.

They are simple in design. KG Deep Groove Ball Bearings are available in a wide range, as defined by the ISO standard plan. These could also be made to meet customer's special dimensional requirements, but within some basic design limitations. These bearings are also available in Stainless Steel material.

Deep Groove Ball Bearings

Deep Groove Ball Bearings are

- Capable of carrying load in either direction, with relatively higher radial load carrying capacity
- Suitable for low or medium load applications
- Suitable for low, medium or even high speed applications; depending on the type and precision of selected Bearing
- Well suited for applications that require high running accuracy
- Suitable for low noise and low torque applications

KG can offer following variants

- Single and Double Row type
- Open basic design type
- As Sealed types
- With Snap Ring groove
- With Snap Ring groove and Snap Ring
- With C2, CN, C3, C4 and C5 radial clearance
- Standard precision grade (ISO Grade 0 - ABEC1) and higher precision grade (ISO Grade 1 - ABEC3)
- With extended Inner Ring
- Pressed Steel, riveted, Plastic and machined Brass Cage
- With stainless steel material with prefix "SS"

Open and closed types (with Metallic -ZZ shields and Rubber Seals-2RS)

Deep Groove Ball Bearings

Apart from the list of items presented in the following pages, many other special type of KG Deep Groove Ball Bearings have been developed to meet specific application requirements. Technical information for such Bearings, is available on request.

KG standard suffixes for Deep Groove Ball Bearings

A	Modified internal design.
C2	Radial internal clearance less than normal.
CN	Normal radial internal clearance. Generally, no special suffix is used in KG Bearings for normal radial internal clearance.
C3	Radial internal clearance higher than normal.
C4	Radial internal clearance higher than C3.
C5	Radial internal clearance higher than C4.
E	Electric motor quality.
G1-G15	KG internal grease type codes. For details, please contact KG International FZCO.
J	Pressed Steel Cage.
K	Tapered bore, with taper of 1:12.
M	Machined Brass Cage.
N	Snap Ring groove in the Outer Ring.
NR	Snap Ring groove in the Outer Ring, with Snap Ring.
P or TN	Plastic / Polyamide / Nylon Cage.
P5	Dimensional and running accuracy confirming to ISO class 5.
P6	Dimensional and running accuracy confirming to ISO class 6.
Q1-Q8	KG internal reference codes. For details please contact KG International FZCO.
RS	Rubber Seal with Steel sheet reinforcement on one side of the Bearing.
RSL	Double lip type Rubber Seal with special groove in the Inner Ring, fixed only at one side of Bearing.
2RS	Rubber Seal with Steel sheet reinforcement on both sides of the Bearing.
2RSL	Double lip type Rubber Seal with special groove in the Inner Ring, fixed at both Bearing sides.
Z	Metallic shield on one side of the Bearing.
ZZ	Metallic shield on both sides of the Bearing.
F	Used as a prefix for a Flange on Outer Ring.

Note: Most of the Bearings listed in the following pages of this chapter are available with above suffixes, subject to design or manufacturing constraints.

Miniature and Extra Small Ball Bearings

Deep Groove Ball Bearings with an outer diameter less than 9 mm are known as Miniature Ball Bearings. Deep Groove Ball Bearings having an outside diameter more than 9 mm, and bore diameter less than 10 mm are known as Extra Small Ball Bearings.

They are available in a wide range, as defined by the ISO standard plan. These types could also be made to meet customer's special dimensional requirements, but with some basic design limitations.

These bearings are also available in Stainless Steel material.

Miniature and Extra Small Ball Bearings are

- Capable of carrying relatively smaller loads
- Suitable for low, medium and high speed applications
- Suited for low noise and low torque applications

Apart from the list of items presented in the following pages, many other special type of KG Miniature and Extra Small Ball Bearings have been developed to meet specific application requirements. Technical information for such Bearings, is available on request.

Magneto Ball Bearings

Magneto bearings have a design similar to a Radial bearing. The groove in the inner ring is a little shallower than that of deep groove ball bearings and one side of the outer ring is relieved. The outer ring have only one shoulder and separable, which makes it convenient for mounting.

Double Row Deep Groove Ball Bearings

It corresponds in design to single row deep groove ball bearings. They have deep uninterrupted raceways and high conformity between the balls and raceways. They are able to carry axial loads acting in both directions in addition to radial loads.

Double row deep groove ball bearings are very suitable for bearing arrangements where the load carrying capacity of a single row bearing is inadequate. For the same outside and bore diameters, double row bearings are slightly wider than single row bearings but have considerably higher load carrying capacity than single row bearings in the 62 and 63 series.

Self-aligning Ball Bearings

Self-aligning Ball Bearings

The Inner Ring of Self-aligning Bearings has two Raceways, and Outer Ring has one spherical Raceway with its centre at the axis of Bearing. These Bearings have a self-aligning character, hence the name.

These Bearings are suitable for applications where small deflection of shaft may occur in usage.

Self-aligning Ball Bearings

Self-aligning Ball Bearings are

- Capable of carrying radial loads, but they are not suitable for axial loads
- Suitable for low or medium speed applications only

KG can offer following variants

- Open basic design type
- Straight Bore and Tapered Bore type
- Sealed type
- With C2, CN, C3, radial clearance
- With extended Inner Ring
- Pressed Steel, machined Brass or Nylon Cage

KG also offers as a set, Tapered Bore Self-aligning Ball Bearings with Adapter Sleeves.

Self-aligning Ball Bearings

KG standard suffixes for Self-aligning Ball Bearings

C2	Radial internal clearance less than normal.
CN	Normal radial internal clearance. Generally, no special suffix is used in KG Bearings for normal radial internal clearance.
C3	Radial internal clearance higher than normal.
G1-G15	KG internal grease type codes. For details, please contact KG International FZCO.
K	Tapered Bore, with taper of 1:12.
M	Machined Brass Cage.
P or TN	Plastic / Polyamide / Nylon Cage.
P5	Dimensional and running accuracy confirming to ISO class 5.
Q1-Q1	KG internal reference codes. For details please contact KG International FZCO.
RS	Rubber Seal with Steel sheet reinforcement on one sides of the Bearing.
2RS	Rubber Seal with Steel sheet reinforcement on both sides of the Bearing.

Note: Most of the Bearings listed in the following pages of this chapter are available with above suffixes, subject to design or manufacturing constraints.

Angular contact Ball Bearings (Single and Double Row)

Angular contact Ball Bearings

Angular Contact Ball Bearings are similar to Deep Groove Ball Bearings, however they can sustain combined radial and axial loads, because the line of contact between the Balls and Raceway is at an angle in the radial plane.

There are three standard contact angle classifications for Single Row Angular Contact Ball Bearings. These have been explained under “ Design and Features of Rolling Contact Bearings” section of this handbook.

Angular contact Ball Bearings

Single Row Angular Contact Ball Bearings can also be used as a combination of two or more units as Tandem (TD), Back-to-Back (BTB) or Face-to-Face (FTF) configurations.

Angular contact Ball Bearings are

- Capable of carrying both axial and radial loads
- Suitable for low, medium and high speed applications

KG can offer following variants

- Open basic design type Single and Double Row Angular Contact Ball Bearings
- As Sealed types
- With Snap Ring groove
- With Snap Ring groove and Snap Ring
- Standard precision grade (ISO Grade 0 -ABEC1) for Single and Double Row Angular Contact Ball Bearings
- Standard as well as higher grade (P6 and P5) for Single Row Angular Contact Ball Bearings used in combination
- Pressed Steel, Nylon Fibre and Brass Cage

Angular contact Ball Bearings

KG standard suffixes for Angular contact Ball Bearings

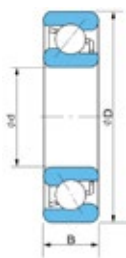

A	Contact angle of 30 degrees.
B	Contact angle of 40 degrees.
C	Contact angle of 15 degrees.
G1-G15	KG internal grease type codes. For details, please contact KG International FZCO.
M	Machined Brass Cage for open type Bearings.
N	Snap Ring groove in the Outer Ring.
NR	Snap Ring groove in the Outer Ring, with Snap Ring.
TN/P	Nylon Cage for open type Bearings.
P4	Dimensional and running accuracy confirming to ISO class 4.
P5	Dimensional and running accuracy confirming to ISO class 5.
P6	Dimensional and running accuracy confirming to ISO class 6.
Q1-Q8	KG internal reference codes. For details please contact KG International FZCO.
RS	Rubber Seal with Steel sheet reinforcement on one side of the Bearing.
2RS	Rubber Seal with Steel sheet reinforcement on both sides of the Bearing.
Z	Metallic Shield on one side of the Bearing.
ZZ	Metallic Shields on both sides of the Bearing.

Note: Most of the Bearings listed in the following pages of this chapter are available with above suffixes, subject to design or manufacturing constraints.

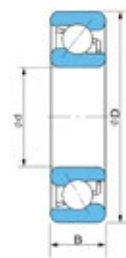

Single Row Series: 70

Four Point contact Ball Bearings

Four Point contact Ball Bearings

Four-point contact ball bearings are radial single row angular contact ball bearings with raceways are designed to support axial loads in both directions and for a given axial load, a limited radial load can be supported.

Four Point contact Ball Bearings

Four point contact ball bearing consist of solid outer rings, split inner rings and ball and cage assemblies with cages.

Due to the two-piece inner rings, a large number of balls can be accommodated. The halves of the inner ring are matched to the specific bearing and must not be interchanged with another bearings of the same size. The outer ring with the ball and cage assembly can be fitted separately from the halves of the inner ring.

Four Point contact Ball Bearings

KG standard suffixes for Four Point contact Ball Bearings

The standard KG offers four-point contact ball bearings comprise in the QJ 2 and QJ 3 series.

KG offers Four Point Contact Ball Bearings with Brass cage but with Steel and Polyamide cage can be developed as per customer requirements.

Note: Most of the Bearings listed in the following pages of this chapter are available with above suffixes, subject to design or manufacturing constraints.

Series: **QJ 200**

Cylindrical Roller Bearings (Single and Double Row)

Cylindrical Roller Bearings

As the name implies, these Bearings have Cylindrical Rollers as Rolling Elements. They form a line contact with the Raceway of Inner and Outer Ring. KG Cylindrical Roller Bearings are produced in many variants, and can also be made as per special dimensional requirements, but within some basic design limitations.

Cylindrical Roller Bearings

Cylindrical Roller Bearings are

- Capable of carrying high radial loads but limited axial loads
- Suitable for medium to high load applications
- Suitable for low and medium speed applications
- Suitable for applications requiring good running accuracy at higher radial loads

KG can offer following variants

- Single Row type - N, NF, NJ, NU and NUP
- Double Row type - NN and NNU (details available on request)
- Higher load capacity - E type
- With Snap Ring groove
- With Snap Ring groove and Snap Ring
- With C2, CN and C3 radial clearance
- Standard precision grade P0 and higher precision grade P6 and P5
- Pressed Steel, machined Brass or Steel Cage
- Straight or Taper bore

Cylindrical Roller Bearings

KG standard suffixes for KG Cylindrical Roller Bearings

A	Modified internal design.
C2	Radial internal clearance less than normal.
CN	Normal radial internal clearance. Generally, no special suffix is used in KG Bearings for normal radial internal clearance.
C3	Radial internal clearance higher than normal.
E	Modified design.
K	Tapered Bore, with taper of 1:12.
M	Machined Brass Cage.
N	Snap Ring groove in the Outer Ring.
NR	Snap Ring groove in the Outer Ring, with Snap Ring.
P5	Dimensional and running accuracy conforming to ISO class 5.
P6	Dimensional and running accuracy conforming to ISO class 6.
Q1-Q3	KG internal reference codes. For details please contact KG International FZCO.

Cylindrical Roller Bearing Design Variants

Note: Most of the Bearings listed in the following pages of this chapter are available with above suffixes, subject to design or manufacturing constraints.

Double Row Cylindrical Roller Bearings

Double Row Cylindrical Roller Bearings of series NN.. and NNU.. types are separable radial bearings. And used as non-locating bearings arrangements in combination with reduced internal clearance.

These bearings are having high radial load capacity and are satisfactory for high speed applications, providing a very stiff and rigid bearing arrangements. They are also commonly used with tapered bores with 1:12 taper with suffix K.

Double Row Cylindrical Roller Bearings

NN TYPE

NNU TYPE

Single Row Series: NU/NJ/NUP/N/NF 2

Needle Roller Bearings

Needle Roller Bearings

The Rolling Elements of Needle Roller Bearings are Cylindrical in shape with the Roller's length being far greater than it's diameter. These Bearings are used where limited space is available between Shaft and Housing.

Needle Roller Bearings

Compared with other types of rolling bearings, needle roller bearings have a small cross-sectional height and significant load-bearing capacity and rigidity relative to their volume. Also, because the inertial force action on them is limited, they are ideal choice for oscillating motion. Needle roller bearings contribute to compact and lightweight machine designs. They serve also as a ready replacement for sliding bearings.

Needle Roller Bearings are

- Capable of carrying high radial loads
- suitable for low and medium speed applications
- mainly used in Gearbox, Steering, Clutch, Differential, Engine, UV joints etc. in Automobiles

KG can offer following variants

- Needle Cages
- Needle Bushes
- Needle Rollers

Needle Roller Bearings

Apart from the list of items presented in the following pages, many other special type of Needle Roller Bearings can be developed to meet specific application requirements. Technical information for Bearings not appearing in our production program is available on request.

KG offers the following types of Needle Roller Bearings

- Needle roller and cage assembly
- Needle roller and cage assembly for connecting rods
- Full Compliment Type
- Drawn-cup needle roller bearing
- Needle bushes
- Needle cages
- Needle bushes

Note: Most of the Bearings listed in the following pages of this chapter are available with above suffixes, subject to design or manufacturing constraints.

Drawn Cup Needle Roller Bearing

Tapered Roller Bearings

Tapered Roller Bearings

The Rolling Elements of this Bearing are Tapered Rollers. They form a line contact with the Raceway of Inner Ring and Outer Ring (Cup). These are separable type Bearings. Tapered Roller Bearings can also be made according to special dimensional requirement, but within basic design limitations. They are available in both metric and inch dimensions.

Tapered Roller Bearings

Tapered Roller Bearings are

- Capable of carrying high radial loads, as well as axial loads in one direction
- Suitable for low and medium speed applications

KG can offer following variants

- Single Row type 302, 303, 303D, 320, 322, 323, 330, 331 and 332 series
- Double Row type -DRT (details available on request)
- Four Row type -FRT (details available on request)
- Precision grade P0 and higher precision grade P6 on request
- Pressed Steel, riveted, machined Brass or Polyamide Cage
- Metric and Inch type

Tapered Roller Bearings

KG standard suffixes for Tapered Roller Bearings

A	Modified internal design.
AR/RA	Flange on the Cup.
D	Used with 303 series to denote equivalence to 313 series in other Brands.
M	Machined Brass Cage.
P or TN	Plastic / Polyamide / Nylon Cage.
P6	Dimensional and running accuracy confirming to ISO class 6.
Q1-Q4	KG internal reference codes. For details please contact KG International FZCO.

Double Row Tapered Roller Bearings

Double row tapered roller bearings can carry heavy loads and are stiff. They are suitable for the accommodation of combined (radial and axial) loads and can locate a shaft axially in both directions with a given axial clearance or a given preload. Their main use is in gearboxes, hoisting equipment, rolling mills and machines used in the mining industry etc

Note: Most of the Bearings listed in the following pages of this chapter are available with above suffixes, subject to design or manufacturing constraints.

Single Row Series: 302

Spherical Roller and Plain Bearings

Spherical Roller Bearings

Spherical Roller Bearings have two Raceways on Inner Ring, and one Spherical Raceway on the Outer Ring. As the name implies, the Rolling Elements of the Bearing have a spherical profile.

Spherical Roller Bearings

Spherical roller bearings have two rows of rollers, a common sphered outer ring raceway and two inner ring raceways inclined at an angle to the bearing axis. The centre point of the sphere in the outer ring raceway is at the bearing axis. Therefore, the bearings are self-aligning and insensitive to misalignment of the shaft relative to the housing, which can be caused, for example, by shaft deflection. Spherical roller bearings are designed to accommodate heavy radial loads, as well as heavy axial loads in both directions.

Spherical Roller Bearings are

- Capable of carrying both radial loads and axial loads
- Suitable for low and medium speed applications
- Suitable for applications where some mis-alignment of Shaft can arise KG can offer following variants
- Single Row type - 202 series (details available on request)
- Double Row type - 213, 222, 223, 230, 231, 232, 239, 240, 241
- Plain type - GE
- With C2, CN, C3 and C4 radial clearance
- Pressed Steel or machined Brass Cage

Spherical Roller Bearings

Apart from the list of items presented in the following pages, many other type of Spherical Roller Bearings can also be developed to meet specific application requirements. Technical information for Bearings not appearing in our production program, is available on request.

MB design

These bearing have fixed rib and machined cages guided on the inner ring rib. **KG can offer this design bearings upon request.**

C design

This bearing have central guide floating on the inner ring, symmetrical rollers with larger dimensions so that the load carrying capacity increases. Special pressed sheet cage. Bearings of this design are of small and medium sizes

CA

These bearings have side shoulders and an one-piece machined brass cage. They also have symmetrical rollers with larger dimensions so that the load carrying capacity increases. This design is available for medium and large-sized bearings **Bearing with Cylindrical bore, lubrication groove and holes in the outer ring**

With withdrawal sleeves

Tapered bore, lubrication groove and holes in the outer ring (taper 1:12, 1:30)

KG standard suffixes for Spherical Roller Bearings

A	Modified internal design.
C2	Radial internal clearance less than normal.
CN	Normal radial internal clearance. Generally, no special suffix is used in KG Bearings for normal radial internal clearance.
C3	Radial internal clearance higher than normal.
C4	Radial internal clearance higher than C3.
C	Pressed Steel Cage.
CA	Machined Brass Cage, one-piece Cage.
K	Tapered Bore, with taper of 1:12.
K30	Tapered Bore, with taper of 1:30.
MB	Machined Brass Cage, split type.
Q1-Q3	KG internal reference codes. For details please contact KG International FZCO.
W33	Oil groove with oil holes in the Outer Ring.

Spherical Plain Bearings

Spherical Plain Bearings (also known as “Spherical Plain Bearings” “Spherical Ball Bushing Bearings” and “Ball Bushings”) have an inner ring with a sphere convex outside surface and an outer ring with a correspondingly sphere, but concave inside surface. Their design makes them particularly suitable for bearing arrangements where alignment movements between shaft and housing have to accommodate, or where oscillating or recurrent tilting movements must be permitted at relatively slow sliding speeds.

Note: Most of the Bearings listed in the following pages of this chapter are available with above suffixes, subject to design or manufacturing constraints.

Series: **213**

Rod end Bearings

Rod end Bearings

Rod ends bearings are intended for linkage applications where a bearing must accommodate significant misalignment. Rod ends offer greater mounting convenience and provide a compact, lightweight, economical design KG offers the industry's widest selection of rod end types and sizes.

Linear Motion Ball Bearings

Linear Motion Ball Bearings (LM)

The linear ball bearing (also called ball bushing or shaft guiding) consists of a polymeric cage with raceway segments made of hardened steel to guide the ball sets within the complete system. Reticulating balls provide unlimited stroke at low friction movement.

KG offers range of Linear Motion Ball Bearings.

Series: **LM**

Thrust Ball, Cylindrical Roller, Spherical Roller Bearings

Thrust Ball, Cylindrical Roller, Spherical Roller Bearings

Thrust bearings are designed to support a predominantly axial load, depending up on type of rolling elements it is classified as Thrust ball bearings, composed of bearing balls supported in a ring, Thrust Cylindrical roller bearings, consist of Cylindrical rollers, Thrust Spherical roller bearings consist of asymmetrical rollers of spherical shape

Rolling elements s are arranged between a set of washers (a shaft washer and housing washer) and the contact angle is 90° .

Thrust Ball Bearings

Thrust Ball Bearings are separable axial bearings that are produced in both single and double direction acting design. To assist in simple effective mounting or dismounting the bearing washers, seating's, and cage and ball assemblies, may be individually mounted in their arrangement location.

Thrust ball bearings may accommodate comparatively high axial loads but they must not be exposed to any radial forces.

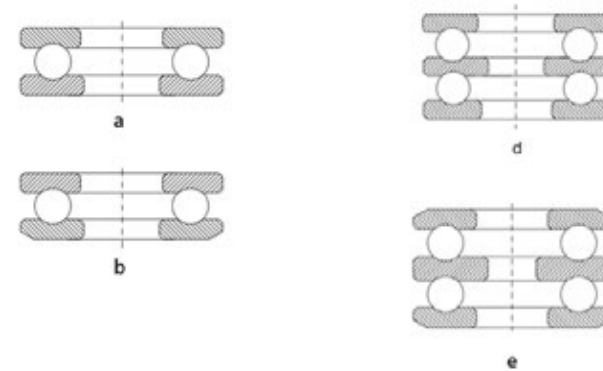

Thrust ball bearings are only suitable for low to medium operating speeds, they require minimum axial loads for their optimum function.

Since thrust ball bearings do not compensate any misalignment, they are also frequently used in conjunction with sphered housing washers and seating washers.

Thrust ball bearings are produced in both, single direction and double direction design.

Single direction thrust ball bearings consist of a shaft washer, a housing washer and a ball and cage (thrust assembly figure a and b of next page). These bearings are able to accommodate axial loads in one direction only. Single direction thrust ball bearings of series 511, 512, 513 and 514 have plain (figure a) and sphered housing (figure b).

Double direction thrust ball bearings are suitable to guide the shaft in both directions (see figure d and e of next page). These bearings consist of two washers, two ball and cage thrust assemblies with one common shaft washer located centrally in between. Double direction thrust ball bearings are also available in both designs, with flat housing washers (figure d) and sphered housing washers (figure e).

Thrust Ball Bearings are

- Capable of carrying only axial loads in one direction or two-directions based on the type selected
- Suitable for low and medium load applications
- Suitable for low and medium speed applications

KG can offer following variants

- Single Direction Thrust Ball Bearing - 511, 512, 513 and 514
- Double Direction Thrust Ball Bearing - 522, 523 and 524
- Single Direction with Spherical Housing Washer - 532,533 and 534

Thrust Cylindrical Roller Bearings

Cylindrical roller thrust bearings are insensitive to shock loading and feature much higher load carrying capacity compared to thrust ball bearings. They accommodate very high axial loads but no radial forces. They provide a very rigid bearing assembly for high thrust loading with less space requirement.

Thrust Cylindrical Roller Bearings are

- Simple design with easy installation
- Suitable for medium and high load applications
- Suitable for medium speed applications

Cylindrical roller thrust bearings are of simple design, they consist of a shaft washer (WS), a housing washer (GS), and a cylindrical roller.

Thrust Spherical Roller Bearings

Thrust roller bearings sustain only axial loads, but they are suitable for heavy loads and have high axial rigidity. Spherical thrust roller bearings contain convex rollers and have a self-aligning capability and are free of any influence of mounting error or shaft deflection. Standard cages are machined brass, pressed cage for high load capacity.

Thrust Spherical Roller Bearings are

- Spherically contoured rollers, arranged in a steep angular position, accommodate high thrust loads and support moderate radial loads.
- Bearing geometry and manufacturing technology result in low friction of bearing.
- Internal self-alignment of bearing elements during operation compensates for shaft deflections and housing distortions caused by shock or heavy loads.

KG standard suffixes for Thrust Bearings

A	Modified internal design.
M	Machined Brass Cage.
P or TN	Plastic / Polyamide / Nylon Cage.
Q1-Q3	KG internal reference codes. For details please contact KG International FZCO.
SC	Special Cage design.

Note: Most of the Bearings listed in the following pages of this chapter are available with above suffixes, subject to design or manufacturing constraints.

Insert Ball Bearing and Ball Bearing Units

Insert Ball Bearing and Ball Bearing Units

Ball Bearing units are simple and economic Bearing arrangements. They offer convenient means to use Rolling Contact Bearings for various applications, without the need of separate Housing to support the Bearing.

Insert Ball Bearing and Ball Bearing Units

Insert Ball Bearing and Pillow Blocks are

- Capable of handling Shaft misalignment (initial errors of alignment) up to a certain degree
- Easy to mount and dismount
- Suitable for low and medium load applications
- Suitable for low and medium speed applications
- Suited for low noise applications
- Generally sealable from both sides; have good protection from the ambient working conditions
- Commonly used in Agricultural Machinery, Conveyor Systems, Food Processing Industry, Packaging Machinery, Construction Equipment and Textile Industry

KG can offer following Ball Bearing Units variants

- Pillow Blocks - UCP, UCPA type
- Square Flange - UCF type
- Flange Cartridge - UCFC type
- Oval Flange - UCFL type
- Take-up Units - UCT type
- AEL types
- Ball Bearing Units with Plastic and Stainless Steel Housings
- Insert Ball Bearings with Stainless Steel

Insert Ball Bearing and Ball Bearing Units

Apart from the list of items presented in the following pages, many other special type of Ball Bearing Units can be developed to meet specific application requirements. Technical information for Bearings not appearing in our production program is available on request.

KG standard suffixes for KG Insert Ball Bearing and Ball Bearing Units

A	Modified internal geometry
G 1 to G6	KG internal grease type codes. For details, please contact KG International FZCO
ND	Special design
NOH	Without oil hole and oil groove on Outer Ring surface
TS	Triple Rubber Seal design
SD	Special location of oil groove and oil holes on Outer Ring surface
WOH	With only oil holes on Outer Ring surface
WOHG	With oil hole and oil groove on Outer Ring surface

Note: Most of the Bearings listed in the following pages of this chapter are available with above suffixes, subject to design or manufacturing constraints.

Plumber Blocks Housings

Plumber Blocks Housings

Plumber Block Housings help to form Bearing units, with Self-aligning Ball Bearings & Spherical Roller Bearings.

They permit flexibility in the choice of Bearing, location on Shaft, Seals & lubrication. Made on modular principle using Cast Iron HT 200 JIS 5501, KG Housings are available in a wide range of sizes to suit various application requirements.

Plumber Blocks Housings

To allow slight adjustment in the position, KG Plumber Block Housings have two elongated holes for attachment bolts. The Bearing seat in the Housing bore is designed for non-locating Bearing arrangements. Bearing can move slightly in either direction to compensate Shaft elongation, which may happen due to thermal expansion.

Different housing variants and seal designs are available, making the use of tailored housings virtually unnecessary and enabling cost effective bearing arrangements to be made.

KG offers

- Low weight to strength ratio
- Ease of mounting and dismounting
- High strength and rigidity

Generally Bearings used in the Plumber Blocks are lubricated with grease, and since it lasts for a longer time, Plumber Blocks do not have re-lubrication holes. However, Bearing performance should be periodically monitored to ascertain re-lubrication requirements.

Special Felt Seals are provided along with KG Plumber Block Housings, for use under normal operating conditions. For more information on use of special Seals, please contact KG International FZCO.

Apart from the list of Plumber Block types presented in following pages, special types can also be developed to meet specific requirements. Technical information for such special Plumber Blocks which do not appear in our regular production program, can be made available whenever required.

Adapter and Withdrawal Sleeves

Adapter and Withdrawal Sleeves

Adapter sleeves are mostly used for locating bearing with tapered bore on cylindrical seating of shafts and it can be located on any position of shaft while Withdrawal sleeve can be used to mount bearings with taper bore on cylindrical seating of stepped shafts.

Adapter and Withdrawal sleeves

- Facilitate mounting of Tapered Bore Self-aligning Ball Bearings, Spherical Roller Bearings, and Cylindrical Roller Bearings, on cylindrical Shafts
- Help to mount Bearings on a smooth Shaft, at any location
- Enable easy mounting and dismounting of Bearings
- Are available for Shafts with both metric and inch dimensions

Adapter and Withdrawal sleeves

Apart from the list of items presented in the following pages, many other special type of Adapter Sleeves have also been developed to meet specific application requirement. Technical information for such sleeves can be made available whenever required

Adapter sleeve

It is most commonly used components for locating bearings with a tapered bore onto a cylindrical seat as they can be used on plain or stepped shafts. They are easy to install and require no additional location on the shaft. When adapter sleeves are used on plain shafts, the bearing can be located at any position on the shaft. Bearings can be accurately positioned axially thereby facilitating bearing mounting and dismounting.

Withdrawal sleeve

To mount bearings with a tapered bore on the cylindrical seat of stepped shafts. The sleeve is pressed into the bore of the bearing inner ring, which abuts a shaft shoulder or similar fixed component. The sleeve is located on the shaft by a *nut or an *end plate.

*Note: Nut or end plate are not supplied along with the sleeve.

Other type of Bearings

Other type of Bearings

Many types of Bearings have been designed to meet the specific requirements of Automotive, Agricultural, Industrial and Other types of applications.

KG has developed numerous Automotive Agricultural, Industrial applications as under

- Wheel Applications
- Clutch Bearings
- Steering Assemblies
- Car Air Conditioners
- Hub Units with and without ABS
- General Automotive and Agricultural Bearings
- Tensioner Bearings
- Alternator Bearings
- Water Pump bearings- they can have either two rows of ball bearings or one row of ball bearings and one row of roller bearings,
- UV joints Bearings (Cross Bearings)
- Special customized Bearings
- Agriculture hub (Agri Hub) bearings
- Agriculture ST Series with round and square bore
- Agriculture PX Series with square bore
- Balls for Industrial applications
- Track Roller Bearings
- Slewing Bearings

Apart from above specially developed Automotive Bearings, many standard Bearings are also used in Automotive applications; few of them are mentioned in following pages.

KG Agri Hub Bearings

The Agriculture Hub is an easy fit compact and integrated solution for agricultural equipment, which is greased and sealed. The hub unit consists of a flanged outer ring that is pre-drilled and taped to accommodate the disc and an Inner ring which is fitted with a threaded stub shaft to enable easy mounting on virtually any implement arm.

Main features of KG Agrihub Bearings

- Optimized interior design
- High capacity bearing with rigid design to withstand shock loads
- High performance sealing to prevent dust, snow, mud, water
- Corrosion resistant to fertilizers and jet cleaning
- Angular Contact Ball Bearings with split inner ring
- Anti-contamination cap for the disc replacement
- Designed to be maintenance free and fit the customer's equipment

More details about **KG Agri hub Bearings** are available on coming pages and **KG Agri Hub leaflet** or you can contact **KG International FZCO**.

KG Slewing Bearings

Slewing rings have a high load carrying capacity, a versatile range of applications and are highly cost-effective. A single slewing bearing can reliably support radial, axial and tilting moment loads. So, in many cases, bearing arrangements comprising a combination of radial and axial bearings can be replaced with a single slewing bearing.

This reduces, in some cases considerably, the costs and work required in the design of the adjacent construction and the fitting of bearings. It is made up of mounting holes, inner gear or outer gear, grease hole and sealing device. It has many positive characteristics: compact structure, light weight, good rigidity, steady speed and high precision.

KG offers following Slewing Bearing variants

- Light Series One Row Ball Bearings
- One Row Ball Flanged Bearing, External Toothed
- One Row Ball Flanged Bearing, Internal Toothed
- One Row Ball Flanged Bearing, Untoothed
- One Row Ball Bearing, External Toothed
- One Row Ball Bearing, Internal Toothed
- One Row Ball Bearing, Untoothed
- Double Row Ball Bearing, External Toothed
- Double Row Ball Bearing, Internal Toothed
- One Row Crossed Roller Bearing, External Toothed
- One Row Crossed Roller Bearing, Internal Toothed
- One Row Crossed Roller Untoothed
- Triple Row Roller Bearing, External Toothed
- Triple Row Roller Bearing, Internal Toothed
- Customized design Slewing Bearings

For more details, please refer to our **KG Slewing Bearing Catalogue and leaflet** or you can contact **KG International FZCO**.

The information and list of Bearings presented in following pages is for reference purposes only.

Apart from the list of items presented, other special type of Bearings have also been developed to meet specific application requirements. Technical information for such Bearings, that do not appear in our regular production program, can be made available whenever required.

If your application requires special bearing boundary dimensions, load ratings and speed, grease we can provide customized bearing solutions. For further information Please contact **KG International FZCO, Dubai**

How to convert:

- To convert 10kgf into N, look for the number 10 on the central column of above table, the corresponding number in 'N' column is the converted value in Newtons.
- Likewise, 10N could be converted into kgf by referring to corresponding entry in kgf column.

Table 4 kgf-lb Conversion Table

kgf		lb	kgf		lb	kgf		lb
0.454	1	2.205	15.422	34	74.957	30.391	67	147.71

How to convert:

- To convert 10kg into lb, look for the number 10 on the central column of above table, the corresponding number in 'lb' column is the converted value in Pounds (lb).
- Likewise, 10lb could be converted into kg by referring to corresponding entry in kg column.

Table 5 °C - °F Conversion Table

°C		°F	°C		°F	°C		°F	°C		°F

How to convert:

- To convert 100 °C into °F, look for the number 10 on the central column of above table, the corresponding number in "°F" column is the converted value in Fahrenheit.
- Likewise, 10° F could be converted into °C by referring to corresponding entry in "°C" column.

Table 6 International Units SI Conversion Table

Category	Name of unit	Symbol	Conversion SI	SI Name of Unit	SI Abbreviations
Angle	Degree	°	$\pi/180$	Radian	rad
	Minute	'	$\pi/10800$		
Length	Second	"	$\pi/648000$	Meter	m
	Meter	m	10^{-6}		
	Micron	μ	10^{-10}		
	Angstrom	Å	1852		
Area	Nautical Mile	mile	1	Square Meter	m ²
	Square Meter	m ²	10^2		
	Radius	a	10^4		
Volume	Hectare	ha	1	Cubic Meter	m ³
	Cubic Meter	m ³	10^3		
Mass	Liter	l	$\approx 1.66057 \times 10^{-27}$	Kilogram	kg
	Kilogram	kg	1		
Time	Ton	t	10^3	Second	s
	Atomic Mass Unit	u	1		
	Second	s	60		
	Minute	min	3600		
Speed	Hour	h	86400	Meter/Second	m/s
	Day	d	1		
Frequency and Oscillation	Meter Per Second	m/s	1	Hertz	Hz
	Knot	kn	1852/3600		
Speed of Rotation	Cycle	s ⁻¹	1	Per Second	s ⁻¹
	Revolution Per Minute	min ⁻¹	1/60		
Angular Speed	Radial Per Second	rad/s	1	Radian Per Second	rad/s
	Meters Per Second Squared	m/s ²	1		
Acceleration	Gravity	G	9.80665	Meters/Second Squared	m/s ²
	Kilogram Force Meter	kgf	9.80665		
	Ton Force	tf	9806.65		
Force	Dyne	dyn	10^{-5}	Newton	N
	Kilogram Force Meter	kgf•m	9.80665		
Moment of Force	Kilogram Force Meter	kgf•m	9.80665	Newton Meter	N•m
	Kilogram Force/Meter Squared	kgf/m ²	9.80665 x 10 ⁴		
	Kilogram Force/Centimetre Squared	kgf/cm ²	9.80665 x 10 ⁶		
Stress and Pressure	Kilogram Force Millimetre Squared	kgf/mm ²	9.80665 x 10 ⁶	Pascal	Pa
	Meter of Water	mH ₂ O	9806.65		
	Millimetre of Mercury	mmHg	101325/760		
	Torr	Torr	101325/760		
Pressure	Atmosphere	atm	101325	Pascal	Pa

	Erg	erg	10^{-7}		
	I.T. Calorie	cal _I	4.1868		
Energy	Kilogram Force Meter	kgf•m	9.80665	Joule	J
	Kilowatt Hour	kw•h	3.600×10^6		
	Metric Horsepower Hour	PS•h	$\approx 2.64779 \times 10^6$		
	Electron Volt	eV	$\approx 1.60219 \times 10^{-19}$		
Power and Dynamic Force	Watt	W	1	Watt	W
	Horsepower	PS	≈ 735.5		
	Kilogram Force Meter/Second	kgf•m/s	9.80665		
Viscosity	Poise	P	10^{-1}	Pascal Second	Pa s
	Centipoise	cP	10^{-3}		
	Kilogram Force/Square Meter	kgf•s/m ²	9.80665		
Kinematic Viscosity	Stoke	St	10^{-4}	Square Meter Per Second	m ² /s
	Centistoke	cSt	10^{-6}		

DISCLAIMER

Due care has been taken in compiling together all words, diagrams, and data tables in this catalogue. The following pages contain information which is meant only for users having requisite technical knowledge and skill in Bearing selection.

Actual conditions for usage are beyond the scope of this work. The selected Bearing's suitability with the intended application must be reviewed by user's engineering personnel or approved by KG's customer support department.

All information provided hereafter is without warranty/guarantee of any kind. KG International FZCO reserves the right to update or change the information herein at any time without notification. KG International FZCO assumes no liability whatsoever for any direct, indirect, incidental, special or consequential losses or damages, arising due to information contained in this catalogue.

The exhaustive range of Bearings included in this catalogue is current at the time of going to print. However, this information might not necessarily be complete, or updated as on the day viewed by the user. Users are advised to contact KG International FZCO for more updated information, or clarifications.
